Anti-Semitism continues to be a widespread societal problem rooted deeply in history. Using novel city-level data from Germany for more than 1,000 cities as well as county-level data, we study the role of economic incentives in shaping the co-existence of Jews, Catholics and Protestants. The Catholic ban on usury gave Jews living in Catholic regions a specific advantage in the moneylending sector. Following the Protestant Reformation (1517), the Jews lost this advantage in regions that became Protestant but not in those regions that remained Catholic. We show that 1) the Protestant Reformation induced a change in the geography of anti-Semitism with persecutions of Jews and anti-Jewish publications becoming more common in Protestant areas relative to Catholic areas; 2) this change was more pronounced in cities where Jews had already established themselves as moneylenders; 3) the Reformation reduced the specialization of Jews in the financial sector in Protestant regions but not in Catholic regions. We interpret these findings as evidence that, following the Protestant Reformation, the Jews living in Protestant regions lost their comparative advantage in lending. This change exposed them to competition with the Christian majority leading, eventually, to an increase in anti-Semitism.

I. Introduction

Anti-Semitism continues to be a widespread societal problem¹ that is deeply rooted in history.² Although a large body of literature has documented the cultural³ and political⁴ determinants of this phenomenon, little has been said about its economic roots. The aim of this article is to document how economic incentives have contributed to shaping the geography of anti-Semitism.

The economic underpinnings of ethnic/religious hostility have a long pedigree in disciplines as different as history, sociology, economics and political science. A large part of this literature has underlined the importance of business and labor rivalries in explaining ethnic conflicts and has focused on the role of labor division as a major determinant of the quality of inter-ethnic relations (see Bonacich (1972, 1973) and Horowitz (1985, p.113)). To the extent that the ethnic division of labor reduces competition among ethnicities in the local labor and product markets, it might also shield societies from internal ethnic tensions. Recently, Jha (2010, 2013) has argued that an ethnic division of labor is sufficient to reduce ethnic tensions when the specific advantage of a certain ethnicity cannot be replicated or expropriated by the others.

Can this theoretical framework explain the emergence and persistence of anti-Semitism? More specifically, can the presence or absence of complementarities in the labor market between the Jewish minority and the majority populations explain the variation in anti-Semitic sentiments and violence over time and regions?

¹ On both sides of the Atlantic, major reports by US and EU bodies confirm that anti-Semitism continues to be a concern (see US Department of State (2005) and European Union Agency for Fundamental Rights (2013)).

² Although the term anti-Semitism was coined in the 19th century, anti-Jewish sentiments and massacres date back to classical times. According to the Roman historian Suetonius, Jews were expelled from Rome in 19 CE. The Jewish philosopher Philo of Alexandria describes an attack on Jews in Alexandria in 38 CE, in which several thousands of Jews were killed. There is evidence of anti-Jewish writings in Alexandria starting from 270 BCE (Feldman (1996)).

³ Voigtländer and Voth (2015) find large effects of the Nazi indoctrination between 1933 and 1945 on the anti-Semitic beliefs of Germans in 1996 and 2006. Voigtländer and Voth (2012) document an exceptional geographic persistence in patterns of anti-Semitism, showing that German cities that experienced anti-Jewish pogroms in 1348 also showed higher levels of anti-Semitism in the inter-war period. Menache (1985) analyzes the importance of the blood libels and the stereotypes of Jews in explaining the expulsion of Jews from England and France in the 13th and 14th centuries.

⁴ Scapegoat theories have long been used to explain outbreaks of violence against the Jews. The theory is that in periods of political and economic distress, politicians find it useful to deflect blame to the Jewish minorities. A large body of empirical literature has documented how anti-Semitism in European history responded to adverse climatic shocks (Anderson, Johnson and Koyama (2015), and Sakalli et al (2016)) and major outbreaks of the Black Death between 1348 and 1350 (Cohn (2007) and Breuer (1988) and Finley and Koyama (2016)).

To answer these questions, we use a natural experiment of history and document a historical episode in which the division of labor between the Jewish minority and the rest of the population had a crucial, causal role in shaping the geography of anti-Semitic sentiments. We focus on German history between 1300 and 1900. In the first two centuries, Jews had a specific comparative advantage in the moneylending sector, which had two main reasons. First, the Catholic ban on usury prevented Catholics from lending at interest, while (starting from the Catholic Council of the Lateran in 1215) allowing the Jews to do so.⁵ Second, literacy rates, numeracy and human capital levels were higher among the Jewish minority compared to the Catholic majority (see Botticini and Eckstein (2007, 2011, 2014)). The main implication was that “the combination of circumstances made serving as moneylenders and pawnbrokers the main occupation of Jews in Germany” (from the entry “Germany” in Encyclopedia Judaica).⁶ Following the Protestant Reformation in 1517, the German lands split between Catholics and Protestants (see Becker and Woessmann, 2009). Protestant views on usury were less restrictive, and Protestant moneylending was allowed (or at least tolerated). Moreover, Martin Luther urged his followers to advance education, reducing the human capital gap between the Jews and the majority population (see Becker and Woessmann, 2011). Hence, whereas in Catholic areas complementarities between Catholics and Jews persisted (and, in fact, were reinforced following the Catholic Council of Trent, held between 1545 and 1563, which equated usury with murder),⁷ in Protestant areas Jews lost their prerogatives in the moneylending sector.

How did this change in complementarities between the Jewish minority and the rest of the population affect Jewish history? We show that following the Protestant Reformation, Jews became more specialized in finance and banking in Catholic Germany compared with Protestant

⁵ Canon 67 of the Lateran Council states, “Jews may not charge extortionate interest”, but they *may* charge interest.

⁶ From the entry “Germany” in the Encyclopedia Judaica (edited by Cecil Roth and Geoffrey Wigoder): “[In the twelfth and thirteenth centuries], the city guilds forced the Jews out of the trades and the regular channels of commerce; this coincided with the stricter appliance of the church ban on usury [...]. Earlier, Israel Abrahams (1896) wrote that “when the medieval Jews devoted themselves largely to commerce and moneylending, they were not obeying a natural taste nor a special instinct, but were led to these pursuits by the force of the circumstances, by exclusive laws, and by the express desire of kings and people.”

⁷ From the Catechism of the Council of Trent: “To this class also belong usurers, the most cruel and relentless of extortioners, who by their exorbitant rates of interest, plunder and destroy the poor. Whatever is received above the capital and principal, be it money, or anything else that may be purchased or estimated by money, is usury; for it is written in Ezechiel: He hath not lent upon usury, nor taken an increase; and in Luke our Lord says: Lend, hoping for nothing thereby. Even among the pagans, usury was always considered a most grievous and odious crime. Hence the question, ‘What is usury?’ was answered: ‘What is murder?’ And, indeed, he who lends at usury sells the same thing twice, or sells that which has no real existence.”

Germany. Moreover, anti-Semitism increased in Protestant Germany relative to Catholic Germany, and this relative increase was more accentuated in areas in which Jewish moneylending was established before the Reformation, serving an important role in the economy.

To document these facts, we use three different datasets.

First, we assemble a large panel dataset on pogroms and other anti-Semitic behavior with observations available every century from 1300 to 1900 for more than 2,000 German cities. We use these data to document that pogroms, the killings of Jews, and expulsions of Jewish communities increased in Protestant Germany relative to Catholic Germany following the Reformation.

Second, we assemble data on all known books and pamphlets published in German cities between 1450 and 1600. We use these data to construct a panel measure of anti-Semitic attitudes in 10-year intervals, and we provide quantitative evidence of the change in these attitudes in Germany following the Protestant Reformation. We find that the number of books with anti-Semitic titles printed in Protestant Germany increased relative to Catholic Germany following the Protestant Reformation.

The fact that the Reformation had a large impact on anti-Jewish attitudes and acts does not necessarily support our theory; that is, the Reformation's large impact on anti-Semitism could have stemmed from many channels unrelated to the division of labor between the Jewish minority and the Christian majority. For example, Martin Luther himself denounced the Jewish people and urged their persecution.⁸ To support our theory, we have collected further city-level data on Jewish moneylending and sectorial specialization of the economy of the city before the Reformation. We use a difference-in-difference-in-differences analysis to show that the increase in anti-Semitism in Protestant areas relative to Catholic areas that followed the Reformation occurred exclusively in those cities in which the Jews had been moneylenders. This result

⁸ In his book "On the Jews and their Lies," Martin Luther proposes the following actions against the Jews: "First, to set fire to their [the Jewish] synagogues or schools [...] Second, I advise that their houses also be razed and destroyed. [...] Third, I advise that all their prayer books and Talmudic writings, in which such idolatry, lies, cursing, and blasphemy are taught, be taken from them. [...] Fourth, I advise that their rabbis be forbidden to teach henceforth on pain of loss of life and limb [...] Fifth, I advise that safe-conduct on the highways be abolished completely for the Jews. For they have no business in the countryside [...] Sixth, I advise that usury be prohibited to them, and that all cash and treasure of silver and gold be taken from them [...] But if we are afraid that they might harm us or our wives, children, servants, cattle, etc., [...] then let us emulate the common sense of other nations such as France, Spain, Bohemia, etc., and eject them forever from the country."

corroborates the view that the ethics of usury played a crucial role in the shift in anti-Semitism following the Protestant Reformation; in cities in which Jews were not moneylenders, the Protestant Reformation had a less pronounced impact. Notice that we do not assume that the cities in which Jews were moneylenders in 1500 are randomly distributed as, in all regressions, we control for city fixed effects and for the interaction between Jewish lending before 1500 and time fixed effects. A potential concern of this analysis is that we might still capture a lower bound of the impact of the Protestant Reformation in cities with Jewish lending. In fact, in these cities, although the rise of business rivalries might have increased anti-Semitism, the presence of a powerful Jewish bourgeoisie might have partially shielded the Jewish minority. To solve this problem, we use new data on the economic specialization of the city before 1500 to capture a measure of “need” for moneylending. We then use these data on sector specialization as instruments for Jewish lending before 1500. In this case, we are *not* assuming that the sector specialization in 1500 of German cities was random. Cities that specialized in different sectors differed across several dimensions, which are captured by the city fixed effects. Moreover, we add sector-by-century fixed effects in the regression to control for the fact that the geography of pogroms might have evolved differently for cities that specialized in different sectors.

In the last part of the paper, we use data on a cross-section of 452 counties in Prussia, the dominant state of the German Empire. We first isolate exogenous variation in Protestantism in the late 19th century using distance to Wittenberg,⁹ where the Reformation was initiated and from where it spread in a concentric way. Second, we find that Protestantism had a negative impact on the size of the local Jewish communities and a strong positive effect on the vote shares for anti-Semitic parties in 1890, 1893 and 1898 in OLS regressions and IV regressions using distance to Wittenberg as instrumental variable. This finding complements our previous findings on the role of the Protestant Reformation in changing the geography of Anti-Semitism. Third, using the 1882 Prussian occupational census, we find that the Reformation exerted a negative effect on the share of Jewish workers in banking and finance. This result is complemented by a set of placebo regressions showing that Protestantism does not “predict” the specialization of the Jews in moneylending in the centuries before the Protestant Reformation. Overall, these findings

⁹ The identification strategy parallels the one used by Becker and Woessmann (2009), who argue that the spread of the Reformation around Luther’s town of Wittenberg captures a part of the variation of Protestantism that is exogenous. They corroborate this identifying assumption by showing that distance to Wittenberg is unrelated to a series of proxies for economic and educational development before 1517.

confirm that the Reformation reduced the comparative advantage of Jews in these sectors in Protestant areas at the same time as comparative advantages persisted in Catholic areas.

In summary, using a combination of city-level and county-level data, we show that the Protestant Reformation induced the following changes: 1) Jewish pogroms, the expulsion of Jews and anti-Semitic attitudes (captured by anti-Jewish publications and votes for anti-Semitic parties) worsened in regions that became Protestant compared to those that remained Catholic. 2) This increase in anti-Semitism in Protestant regions was more accentuated in regions in which Jewish moneylending had been established before the Reformation. 3) Jewish involvement in finance and banking decreased in the Protestant regions relative to the regions that remained Catholic.

We interpret these findings as evidence that with the Reformation, the Jews lost their comparative advantage in lending. This change exposed them to competition with the Christian majority and led to an increase in ethnic and religious hostility toward the Jews.

The paper proceeds as follows. Section II gives the historical background. Section III presents our data sources. Section IV gives the empirical results at the city level. Section V exploits the cross-sectional data on Prussian counties. Concluding remarks close the paper.

II. Historical background and Previous Literature

In the first three centuries CE, there is no evidence of a systematic Christian ban on usury. It was in the First Ecumenical Council at Nicaea in 325 AD that the prohibition against usury entered Canon Law. The prohibition was limited to the clergy, and usury was defined as excessive interest.¹⁰ Charlemagne extended the definition of usury to every loan that charged interest (“where more is asked than is given”) and prohibited usury to everyone in his empire. With the Synod of Pavia in 850 AD, this prohibition entered Canon Law.¹¹ The Second (1139)

¹⁰ Canon 17 in the First Council of Nicaea: “Forasmuch as many enrolled among the Clergy, following covetousness and lust of gain, have forgotten the divine Scripture, which says, He has not given his money upon usury, and in lending money ask the hundredth of the sum [as monthly interest], the holy and great Synod thinks it just that if after this decree any one be found to receive usury, whether he accomplish it by secret transaction or otherwise, as by demanding the whole and one half, or by using any other contrivance whatever for filthy lucre’s sake, he shall be deposed from the clergy and his name stricken from the list.”

¹¹ The Synod of Pavia prescribed excommunication of lay usurers and called for restitution of interest to their victims.

and the Third (1179) Lateran Councils strongly reaffirmed the interest ban.¹² The immorality of interest was also asserted by St. Thomas Aquinas.¹³ This put a tight lock on the practice of usury, “which would put the church in a theoretical bind for centuries because his writings were considered among its highest philosophical and theological teachings” (Geisst, 2013, p. 51).

Canon Law applied to the Catholics. In the words of Geisst (2013, p.23), “as canon law developed, an ‘otherness’ would come to characterize Jews and other moneylenders¹⁴ who did not follow the precepts of the church.” Jewish moneylending was tolerated. In fact, by forbidding the Jews to lend for an immoderate profit,¹⁵ the Fourth Lateran Council (1215) de facto authorized them to lend for a moderate profit. Why did the Catholic Church tolerate Jewish usury? St. Thomas Aquinas gives the answer in the Summa Theologica: Jews were permitted to lend money to avoid the even greater danger that Christians would practice usury¹⁶ (Geisst 2013, p. 51; Poliakov, 1977, p.26).

Starting from the 12th and 13th century, moneylending and pawnbroking became the main occupations of the Jews¹⁷. The main specialization of Jews in German regions continued to be in finance and banking until the 19th century (see Appendix B for a complete set of citations about Jews and moneylending in German history from the Encyclopedia Judaica).

¹² Canon 13 in the Second Lateran Council: “We condemn that practice accounted despicable and blameworthy by divine and human laws, denounced by Scripture in the old and new Testaments, namely, the ferocious greed of usurers; and we sever them from every comfort of the church”. Canon 25 in the Third Lateran Council: “Nearly everywhere the crime of usury has become so firmly rooted that many, omitting other business, practice usury as if it were permitted, and in no way observe how it is forbidden in both the Old and New Testament. We therefore declare that *notorious* usurers should not be admitted to communion of the altar or receive Christian burial if they die in this sin.”

¹³ This is the answer given by St. Thomas Aquinas in the Second Part of the Summa Theologica (1274) to the question of whether usury is a sin: “To the objection, that a man may take a price for what he is not bound to do; but a man with money is not in every case bound to lend it, it is to be said that he who is not bound to lend may receive compensation for what he has done in lending, but ought not to exact more. But compensation is given him according to the equality of justice, if the exact amount is returned to him that he has lent.”

¹⁴ Jewish moneylenders were competing in the Middle Ages with the Lombards and Cahors. Originally, these two groups were Arians and, as such, did not acknowledge the Council of Nicaea. They were considered heretics and therefore fell outside Canon Law (Geisst, 2013, p. 23).

¹⁵ Canon 67 in the Fourth Lateran Council: “Wishing, therefore, in this matter to protect the Christians against cruel oppression by the Jews, we ordain in this decree that if in the future under any pretext Jews extort from Christians oppressive and immoderate interest, the partnership of the Christians shall be denied them till they have made suitable satisfaction for their excesses.”

¹⁶ “As for their taking usury of strangers, that was not granted them as a thing lawful, but permitted for the avoidance of a greater evil” (Aquinas, 1274).

¹⁷ A similar transition of Jews from their traditional occupations (dyers, silk weavers and traders) to moneylending occurred in Italy. For a detailed description of the Italian context, see Pascali (2016).

The historical literature has emphasized two different motives that explain this phenomenon: 1. the Catholic tolerance towards Jewish lending discussed above 2. the high levels of human capital among the Jews (Botticini and Eckstein (2007, 2011, 2014)).^{18 19}

With the Protestant Reformation, the German religious landscape changed dramatically. After a period of turmoil following the start of the Reformation in 1517 in Luther's city of Wittenberg, the Imperial Diet held in 1555 in Augsburg adopted the principle "Cuius regio, eius religio" ("Whose rule, his religion"). This meant that denominational choices were made only by the rulers of the large number of territories that constituted the fragmented German Empire at the time of the Reformation.²¹ The Reformation brought about two important changes with respect to moneylending and the relationship between Christians and Jews. First, Jones (2004, p.87) argues that Luther "was principally opposed to lending money at interest, but made provisions for the practise, Calvin supported and defended the habit of usury, except in a few inherently unloving circumstances." Protestants were thus allowed (or at least tolerated) to engage in moneylending (see also Hattenhauer, 2015). Second, Protestants, with their emphasis on education, acquired human capital that equipped them with the education necessary to enter highly skilled occupations such as moneylending.²²

The combination of these factors in Protestant areas might have disrupted the inter-ethnic complementarities that existed between Jews and Christians (who were all Catholic before the Reformation).²³ In a sense, the Reformation made Jews "redundant" in the moneylending business in Protestant areas, whereas they continued to provide inter-ethnic complementarities in

¹⁸ The path-breaking research of Botticini and Eckstein covers the time until 1492, before the Protestant Reformation, and takes a worldwide perspective. It stresses that early specialization of Jews in urban occupations was the result of their higher levels of human capital with respect to the Christian population. Starting from the 7th century, whereas the rest of the population was illiterate, all Jewish men were literate because of an education reform of the first century CE. "Why were Jewish farmers (and Jews in general) literate whereas the rest of the rural population was illiterate at the beginning of the seventh century? The Jewish religion made primary education mandatory for boys in the first century when the high priest Joshua ben Gamala issued an ordinance that teachers had to be appointed in each district and every city and that boys of the age of six or seven should be sent."

¹⁹ Other authors have emphasized the fact that the city guilds forced the Jews out of their traditional occupations in German cities in the 12th and 13th centuries. See Ogilvie (2014).

²¹ See Spenkuch (2017) who uses these denominational choices as a source of exogenous variation for long-run outcomes.

²² See Becker and Woessmann (2009) for historical details and long-term consequences of the Reformation on literacy and economic development from a regional perspective.

²³ It should be stressed that in Germany, Protestantism is mostly of the Lutheran type. For instance, in Prussia (the largest state by far), Lutherans constitute 94% of all Protestants, and only 6% of Protestants are Reformed Protestants. However, there are larger numbers of Calvinists in Southern Germany. As mentioned earlier, Luther's and Calvin's views on usury differed (see Jones, 2004), at least in their emphasis or toleration of everyday practice.

banking in Catholic areas. In fact, in Catholic areas, the interest ban was, if anything, strengthened²⁴ during the Counter-Reformation, and it survived until the 18th century.²⁵

According to our hypothesis, this should have led to a relative increase in anti-Jewish acts in Protestant areas versus Catholic areas following the Protestant Reformation, and this increase should have been driven by areas in which Jewish lending had been more relevant to the local population.²⁶ In the empirical section, we document the impact of the Reformation on the involvement of the Jewish minority in finance and banking. We also document anti-Jewish acts over the centuries and consider whether there was a changing pattern across Protestant and Catholic areas and across areas with more or less “need” for lending following the Reformation.

The only other (recent) working paper we are aware of that empirically studies a link between pogroms and moneylending is Sakalli et al. (2016).²⁷ Their paper looks at pogroms between 1800 and 1939 in the Pale of Settlement, where Jews were confined to live within the Russian Empire. Their results show that pogrom intensity in response to weather shocks are more pronounced in localities with a greater Jewish concentration among creditors.

III. Data and Descriptive Statistics

In the empirical section of this paper, we test three hypotheses: 1) the Protestant Reformation induced more killings of Jews, expulsions of Jews and anti-Jewish publications in

²⁴ De Roover (1948) writes, “In the sixteenth century, however, a reaction set in, apparently in an attempt to counteract the spread of the Reformation. The Church reaffirmed its traditional doctrine on the matter of usury and reverted to the uncompromising attitude, which had prevailed prior to the fifteenth century. The secular authorities, however reluctantly, continued to issue licenses, but the Church henceforth refused to grant dispensation to the Lombards. They were, and remained, excommunicated. According to Charles V's ordinance of January 30, 1546 (n.s.), licensed usurers were forbidden to attend mass or to enter any church under the penalty of forfeiting their licenses. The same prohibition applied to anyone who was in partnership with them, who owned a share in their *tables de prêt*, or who participated in their management” (De Roover, 1948: 151).

²⁵ In 1745, in the *Encyclica Vix Pervenit*, Pope Benedict XIV writes, “The sin [in usury] rests on the fact that sometimes the creditor desires more than he has given. Therefore he contends some gain is owed him beyond that which he loaned, but any gain which exceeds the amount he gave is illicit and usurious.” In the following years, the Catholic definition of usury changed. Starting from the work of Scipione Maffei (whose “*Dell' impiego dell danaro*”, i.e. “On the use of money”, was widely discussed), usury is defined as “any increment – not beyond the principal – but beyond the moderate rate allowed by law or customs. The new definition represented a radical departure from the basic norms of scholastic economics” (De Roover, 1955). Finally, in 1830, the Church too abandoned punishment of usurers, although it did not formally revoke the usury doctrine (see Geisst, 2013).

²⁶ Notice that even before the Reformation, Jews were by no means sheltered from attacks. Pogroms against Jews broke out occasionally, such as after the Black Death in 1348–50, for which Jews were partly blamed.

²⁷ Finley and Koyama (2016) look at how political rule affected regional variation in the intensity of Black Death pogroms. They consider revenue generated by Jewish moneylending as a primary source of conflict, but do not employ any measure of moneylending.

the regions that became Protestant relative to the regions that remained Catholic; 2) this change was related to the fact that Jews lost their prerogatives in moneylending, and therefore it was accentuated in cities in which Jewish moneylending was established before the Reformation; and 3) Jewish involvement in finance and banking decreased disproportionately more in the Protestant regions than in the Catholic regions.

To empirically test these hypotheses, we need a wealth of data. We discuss various data sources in turn and provide more detailed information on how we coded key variables in the Data Appendix.

III.A. City-level data: 1300-1900

Our main sources for data about Jewish communities in Germany are *Germania Judaica* (1963–2009) and Alicke (2008). We consult the *Encyclopedia Judaica* (2007) for comparison as it only covers the largest Jewish communities, whereas *Germania Judaica* and Alicke cover all Jewish communities, large or small. *Germania Judaica* covers the period before the Reformation, whereas Alicke covers the entire period and thus constitutes our main source for the post-Reformation period. *Germania Judaica* is richer in breadth and allows us to measure, for instance, Jewish moneylending before the Reformation, which we use in our analysis. Anti-Semitic acts and Jewish presence are the key variables in our basic set of regressions. Other city-level data come from the *Deutsches Städtebuch*, a series of volumes edited by Erich Keyser (1939–1974) that provide information on each city in the German Empire incorporated prior to the compilation of the *Städtebuch*. The *Städtebuch* covers 2,344 cities. We follow Cantoni and Yuchtman (2014) and exclude cities outside the Holy Roman Empire (dropping 90 cities in East Prussia). In our main estimation sample, we use those cities that were founded before 1500 (i.e. existed before the Reformation) and that have a recorded Jewish presence at least once over the years 1300-1900, making for 1,274 cities in our main analysis. These cities are depicted in **Figure A.1**. In robustness checks, we use all cities recorded in the *Städtebuch*. For symmetry, we use two centuries before the Reformation (1300-1500) and two after the Reformation (1500-1700) in our main analysis, but again we show that results are robust when using four post-Reformation centuries (1500-1900). We now describe these sources and include details of the coding of variables in the Data Appendix.

1. Germania Judaica

We use volumes 2 and 3 of *Germania Judaica*, covering the centuries before the Protestant Reformation. These books contain city-level information for all Jewish settlements in the German Empire. Data collection started at the beginning of the 20th century and was initiated by the “Society for the Advancement of Jewish Studies” (*Gesellschaft zur Förderung der Wissenschaft des Judentums*). City-specific articles were drafted by a consortium of historians from across the German Empire to facilitate access to local archival sources. Volume 1, covering the years until 1238, was completed before World War II, and work on volumes 2 and 3 resumed after World War II. Voigtländer and Voth (2012) introduced *Germania Judaica* into the economics community. To be precise, they used volume 2. We go beyond their work by using a more extensive list of cities (to link the data with all cities covered in the *Deutsches Städtebuch* described below). We code information on pogroms not only in 1348-49 but at any point in the 14th and 15th century and beyond, using *Germania Judaica* 3 as well.²⁸ We also code information about Jewish lending. Specifically, we define, century by century, the following variables: a) Jewish presence (minor Jewish settlements of less than 10 families and larger Jewish communities of 10 or more families); b) the persecution of Jews (expulsion of parts of the Jewish community; expulsion of the whole community; killings of parts of the Jewish community; killings of the whole Jewish community); and c) Jewish lending activity. Of course, absence of proof of Jewish lending activity is not proof of absence, but to our knowledge, *Germania Judaica* is the best available data. Note that we choose to code data century by century because the sources often do not provide more precise information than that. In some cases, entries might only state that there is “evidence of a Jewish community during the x-th century.”

2. Alicke (2008)

Because the *Germania Judaica* project has only covered the period until 1519 (up to the Reformation), we draw on Alicke (2008) for the later centuries. This source was first introduced in the economics literature by Voigtländer and Voth (2012). It is an equally impressive collection of more than 4,600 pages on Jewish history covering thousands of cities. We use it to code Jewish presence and the persecution of Jews in the post-Reformation period in the same way as we do with *Germania Judaica*. Unfortunately, Alicke does not capture Jewish lending activity in

²⁸ In robustness checks, we drop Black Death pogroms and show that results are not driven by this prominent pogrom wave.

a systematic way. Again, the Data Appendix gives examples of the coding of our variables based on Aliche.

3. *Deutsches Städtebuch*

The *Deutsches Städtebuch* is our source for variables that enter our regressions either as control variables or as instrumental variables. Anti-Semitism might be “collateral damage” of war activity in which cities are involved. We code information from the *Städtebuch* to capture whether there was a battle near a city; whether the city was besieged, sacked, partially destroyed, completely destroyed, or occupied; or whether the city was involved in a war elsewhere.

To the extent that Protestant Reformers emphasized education (see Becker and Woessmann, 2009), education may have increased or decreased anti-Semitism depending on whether more educated Protestants increasingly competed with already well-educated Jews or whether education helped to reduce conflict potential. The *Städtebuch* contains information about the presence of a school, which is the best indicator available to capture schooling in a city. Specifically, for each city/century we record whether there is any evidence of the presence of a primary or secondary school. Especially in the early centuries, the great majority of these schools are primary church schools.

Pogroms may be more likely to happen in larger cities if larger populations can be equated with a higher probability of inter-religious conflict. The *Städtebuch* has population data for less than half of all city-by-century observations, so this particular analysis is limited to an unbalanced panel of cities for which population data are available. We experimented with the population data in the *Städtebuch* and results are robust to the inclusion of population variables from this source (see the working paper version (Becker and Pascali, 2016)). However, we now present population data as used in Cantoni (2015) which are drawn from Bairoch, Batou and Chevre (1988) for a smaller set of cities because the Bairoch et al. data are more widely known and established.

To the extent that lending activity was more important in some cities than in others, depending on the sector specialization, we code information about salient industries, as described in the *Städtebuch*. We use sector specialization before the Reformation as instrumental variables to predict Jewish lending activity before the Reformation. The Data Appendix gives examples of how we code these variables.

Table 1, Panel A shows descriptive statistics for the sample of 1,274 cities over four centuries (i.e., for 5,096 observations). For instance, on average, 6.8 percent of city-century observations have evidence of a Jewish community of 10 families or more. Importantly, the share of city-century observations with evidence of any Jewish presence, also fewer than 10 families, is considerably higher (43.2 percent on average). Table 1 also shows that on average, 15.5 percent of city-century observations have evidence of any pogroms (i.e., killings or expulsions of Jews). Appendix **Table A.1** shows those indicators century by century. Additionally, Table A.1 shows data separately for Protestant and Catholic cities (defined on the basis of whether a city was Protestant or Catholic in 1546; we explain the origin of this definition further below). In the 14th century, 51 percent of cities show evidence of a Jewish presence, compared to just 11 percent with a Jewish community of 10 or more families. Interestingly, both Protestant and Catholic cities have very similar shares of Jewish presence and Jewish communities over all centuries. Yet, Table A.1 also documents a cross-over in the incidence of pogroms between the two pre-Reformation centuries (1300-1400 and 1400-1500) to the two post-Reformation centuries (1500-1600 and 1600-1700). While pogroms are more prevalent in Catholic cities before the Reformation, this changes during the 16th century. **Figures A.2 to A.5** show the geographic distribution of cities with Jewish communities and pogroms over four centuries (while **Figures A.6 and A.7** extend the data to the 19th century). Going back to Table 1 and turning to military conflicts, the most common type are sackings, which affect 11.6 percent of city-by-century observations. There is evidence for the presence of a school for 43.8 percent of city-by-century observations for which there is information on schools in the *Städtebuch* (4,920 out of 5,096 observations). Table A.1 shows the school information by century and separately for Protestant and Catholic cities. Finally, population information based on Cantoni (2015) for 395 city-by-century observations, range from 1,000 inhabitants (the smallest population size recorded in Bairoch et al.) to 80,000 in the 17th century.

Table 1, Panel B presents a cross-sectional view of the same set of 1,274 cities for variables for which we use no variation over time. Protestant in 1546 is a dummy variable based on a detailed map in Zeeden (1984) showing the denomination of the ruler in the year 1546, which we digitized. This map underlies the maps displayed in Figures A.1.-A.8. We would like to stress

how detailed and accurate the map by Zeeden is.²⁹ Consider, for instance, Figure A.1. and take the city of Lindau, in the very South of Germany, at the Eastern edge of the Lake of Constance (Bodensee). It is the one red/Protestant area (Lindau's jurisdiction extended to some neighboring villages) at the Southern border of (modern-day) Germany, surrounded by all-blue (Catholic) territory, and shows that Lindau, which adopted the Reformation in 1528, is accurately shown as Protestant. Similarly, the city of Memmingen just a bit to the North-East of Lindau, shows as Protestant. In the north of Germany, the Zeeden map shows Parchim as a Protestant city in otherwise Catholic territory, in line with its adoption of the Reformation in the year 1530.³⁰

Just over half of the 1,274 cities had a Protestant ruler in 1546. Jewish lending activity before 1500 is documented for 21.4 percent of the cities, or just under half of the cities with any presence of Jews (see Table A.1, showing a share of 51 percent of cities with Jewish presence in the 14th century and 45 percent in the 15th century.) The cities with documented Jewish lending before 1500 are displayed in **Figure A.8**. As for the sector structure of cities, 39.1 percent of cities have evidence of manufacturing before 1500, 19.6 percent list agriculture as a salient sector, 21.8 percent were important trading cities, and 3.3 percent mention other salient (service) sectors.

One might worry that there is a systematic difference in record-keeping of city histories between Protestant and Catholic cities. **Table A.2** compares the length of entries in the *Deutsches Städtebuch* between Protestant and Catholic cities. The average length of entries is 3 pages for all cities, with Catholic cities, if anything, having marginally longer entries. While we did not perform a similar exercise for length of entries in the *Germania Judaica*, it seems unlikely that differences in pogrom intensity between Catholic and Protestant cities is driven by differences in reporting.

III.B. Anti-Jewish sentiment in books: 1450-1600

The Universal Short Title Catalogue (USTC) produced at the University of St. Andrews (2012) is the primary source of data on book and pamphlet editions that were published around the

²⁹ A scan of the original multi-color map is available from us on request, but we cannot include it in the paper for copyright reasons.

³⁰ Still, to further show that our results do not rely exclusively on the coding of cities as Protestant or Catholic based on one particular map, we re-run our analysis on the smaller set of cities used in Cantoni (2012) who hand-coded cities as Protestant or Catholic based on various sources. Our results are unchanged. We are grateful to Davide Cantoni for sharing his data with us.

Protestant Reformation. The USTC is designed as a universal catalogue of all known books printed in Europe in 1450-1600 and provides information for each book on the city in which it was published, the language and the year of publication.

Data on the number of anti-Jewish books published in each city/decade were constructed as follows. First, we downloaded the USTC catalogue for all books in German and Latin that were published in the cities in our sample. We identified a total of 88,517 books with complete information about the city and year of publication (40,758 in German and 47,759 in Latin). Second, we identified 5,000 books in the USTC that were clearly not anti-Jewish. Third, we used Christian Wolf's (1715) *Bibliotheca Hebraea*, a comprehensive catalogue of books printed before 1715 that has a dedicated section listing anti-Jewish content, to identify 201 anti-Jewish books published in either Latin or German. Fourth, we used the books identified as either anti-Jewish or not (the "training sample") to measure the distribution of words across the two categories of books, following the same logic as the seminal work by Dittmar and Seabold (2015). Generally, the titles of these books provide extended descriptions of the contents.³¹ This allowed us to determine which features of language are important in identifying anti-Jewish books. Fifth, we used the Naïve Bayesian text algorithm to construct a ranking of books based on their probability of being anti-Jewish. Finally, we computed the total number of books in each city/decade that were classified among the top 0.2 percent³² in terms of probability of being anti-Jewish.

The naïve Bayesian classifier is a probabilistic classifier that applies Bayes' theorem to compute the probability that a certain text pertains to a certain category under the assumption that words are conditionally independent of each other.³³ For instance, assume that a title is made of n words $X_1..X_n$; then,

$$\frac{P(\text{antiSemitic} | \text{title}=X_1..X_n)}{P(\text{book antiSemitic})} = \frac{\prod_{i=1}^n P(X_i | \text{antiSemitic})}{\prod_{i=1}^n P(X_i)}. \quad (1)$$

³¹ The median title in our data has 22 words (mean=23.77) and 160 characters (mean=176.77). See **Table A.3** in the Appendix.

³² We choose this value because it minimizes the probability of classifying a book as either being anti-Jewish when it is not or not being anti-Jewish when it is within the training sample. In all the regressions, the choice of this cut-off affects the estimated constant but not the other coefficients.

³³ Many empirical comparisons between naïve Bayes and more complicated decision tree algorithms showed that the naïve classifier is one of the most efficient and effective classifiers for machine learning and data mining, even if the conditional independence assumption is rarely true in real-world applications (see Kononenko (1990), Langley, Iba and Thomas (1992), and Pazzani (1996)). Recent articles have shown that there are sound theoretical reasons for the apparently implausible efficiency of naïve Bayes classifiers (see Roth (1999), Hand and Yu (2001) and Zhang (2004)).

Notice that $P(X_i | \text{antiSemitic})$ and $P(X_i)$ can be computed for every i once we have defined an initial set of books that are anti-Jewish and an initial set of books that are not. We then use the estimated $\frac{P(\text{antiSemitic} | \text{title}=X_1..X_n)}{P(\text{book antiSemitic})}$ to construct a ranking of books from those with a higher probability of being anti-Jewish to those with the lowest probability.

To understand the type of books that are categorized among the top 0.2 percent in terms of probability of being anti-Jewish by the algorithm, here are some examples:³⁴

- *"De veritate fidei christianae libri quinque in quibus de religionis nostrae fundamentis contra Ethicos Judaeos Agarenos sive Mahumetanos et perverse christianos plurima subtilissime simul atque exactissime disputantur."*³⁵

- *"Epistola contra Judaeorum errors."*³⁶

- *"Ratschlag ob Christlicher Obrigkeit gebueren muege das sie die Jueden unter den Christen zu wonen gedulden und wo sie zu gedulden welcher gestalt und mass."*³⁷

- *"Frage. Ob ein rechtgleubiger Christ mit Unchristen als mit Juden Tuercken heiden oder mit offentlichen uberfuerten ketzern muege Buergerliche gemeinschaft haben mit inen essen und trincken"*³⁸

There is a printing of at least one edition of a German or Latin language book in 149 German cities over the decades 1451-1600, and in 108 cities at least 10 editions are printed over this period (see **Figure A.10**). As shown in **Table 1, Panel C**, the average number of books printed per city-by-decade observation is 39.6, ranging from zero in decades without printing to 1,433 editions in just one decade in the most print-active city. The average number of editions with predicted anti-Semitic content is 0.118, ranging between zero and 9 editions. Our main estimation sample for the analysis of book titles is the set of cities that have at least 20 book editions over the decades 1451-1600, a total of 95 cities, for 1,520 city-by-decade observations (see Table 4, column 2). Our main regressions in Table 4 restrict the sample to cities which have

³⁴ **Figure A.9** reports the word cloud for anti-Jewish Latin books. Not surprisingly, the most common words are "Contra" and "Iudei" ("Against" and "Jews"). Among the most frequent words, we also see "Errores" ("Mistakes"), "Adversus" ("Enemy"), "Perfidia" ("Perfidy"), "Foenore" ("Usury"), and "Infidels" ("Infidels").

³⁵ "Five books on the truth of the Christian faith, which discuss the fundamentals of our religion against Pagans, Jews, Muslims and on the side of the Christians in a keen and accurate way."

³⁶ "Letter against the Jewish mistakes."

³⁷ "Advice as to whether Christian rulers should permit Jews to live among Christians and where and to what extent they might be tolerated."

³⁸ "Question. Whether a righteous Christian should be allowed to have community or eat and drink with non-Christians such as Jews, Turks and heathens or with convicted heretics."

the same religion as the surrounding territory. The rationale is that we expect readership to come both from the printing cities themselves, but also from the surrounding countryside. If printers cater to the demand of a readership that is of a different denomination in the city than in the surrounding countryside, results are likely to be affected. There are 74 cities with at least 20 book editions where city and surrounding countryside are of the same denomination. We run robustness regressions on the set of cities with at least one, at least 50 and at least 100 print editions in 1451-1600.

III.C. Prussian county data at the end of the 19th century

For the post-Reformation period, we also draw on Prussian census data (Becker et al. 2014) to study, in one cross-section, in more details, the link between Protestant Reformation, occupational specialization and anti-Semitism. The county-level data available for Prussia in the 19th century are generally viewed as a unique source of highest-quality data for micro-regional analyses (Galloway, Hammel, and Lee (1994)). Data during the 1880s and 1890s are available for 452 counties, displayed in **Figure A.11**. The Prussian Occupation Census of 1882 contains information on the number of Catholics, Jews, and Protestants in the population and in the work force in different occupations. The simplest and most obvious outcome is to look at the share of Jews in the county population to capture the residential pattern of Jewish communities at the end of the 19th century. This can be seen in **Figure A.12**. In contrast to our city-level dataset, for which we were only able to code binary indicators for the presence of small or large Jewish communities, the Prussian census data provided exact head counts³⁹. The Occupation Census also allowed us to compute the degree of occupational specialization of various religious groups. Our main outcome variable to capture Jewish occupational specialization in finance was the share of those working in “banking and insurance” (briefly, finance) who were Jews. As the descriptive statistics in **Table 1, Panel D**, show, the average share of Jews in finance across Prussian counties was 9.4 percent, which must be compared with the share of Jews in the Prussian population of only 1.1 percent. **Figure A.13** displays the regional distribution of this variable. The Occupation Census gives separate data on banking and insurance and has two

³⁹ We can use the Prussian Census data to check whether different data sources correspond to each other. In **Table A.4**, we regress the share of Jews in a Prussian county, according to Prussian census data, on the share of cities in the county which are listed in Aliche (2008) as having a Jewish community in 1800-1900. The results attest to the fact that both sources line up.

hierarchical levels: the higher hierarchical level is labeled “self-employed and directors,” and the lower level includes all other employees. Table 1 reveals that among the self-employed and company directors in banking alone, Jews constituted 27.5 percent, on average. **Figure A.14** displays the regional distribution of this variable.

We run regressions with and without control variables. These are drawn from the 1871 Population Census previously used by Becker and Woessmann (2009). Control variables are the share of the population aged below 10, the share of females, the share born in the municipality, the share of Prussian origin, average household size, log population size, a dummy variable for counties that are currently in Poland, and the share of the county population living in urban areas.

Election results for anti-Semitic parties are also important outcomes of interest. We use election results for the German Reichstag elections in 1890, 1893 and 1898. In 1890, for the first time, the anti-Semitic party stood for election to the Reichstag and was listed in the sources as *Anti-Semiten*. After being renamed, it was listed in 1893 as *Deutsche Reformpartei (Anti-Semiten)*. In 1898, three anti-Semitic parties ran in the German Empire, but sources report their total vote count as *Anti-Semiten (Deutsche Reformpartei, Anti-Semiten, Christlich-soziale Partei)*. We are interested in studying in which precincts candidates of those parties first stood for office (the extensive margin) and the vote share they obtained (the intensive margin). **Figures A.15, A.16 and A.17** display the regional distribution of votes for anti-Semitic parties in 1890, 1893, and 1898.

IV. Results based on city-level data

Our discussion of city-level data is presented in two parts. First, we show how pogroms against Jews changed over the course of six centuries in a basic difference-in-differences setup without control variables. We then probe the robustness of these results with respect to three factors: a) military conflict; b) education; and c) city size. Then, we consider the decades before and after the Reformation by examining anti-Jewish sentiment based on the titles of books printed in Protestant and Catholic cities across Germany to document the geographic shift in anti-Semitic sentiment before and after 1517 in towns with printing presses. We then return to the larger set of cities and consider economic factors involved in the shift in anti-Semitism from Catholic to Protestant cities in the century before and after the Reformation.

IV.A. City-level data: 1300-1700

Before presenting regression results, **Figure 1** displays the pogrom intensity, separately for Catholic and Protestant cities. One can note the overall decline, over the centuries, in the pogrom intensity, which is in line with the secular decline in violent crime discussed in Eisner (2003).⁴⁰ Note that the important exception from this overall downward trend occurs in Protestant cities during the Reformation century from 1500-1600, where pogrom intensity goes up and overtakes that in Catholic cities.⁴¹

A similar pattern is described by Figures A.2 to A.5, which again describe the location of pogroms every century from 1300-1700. In the centuries 1300-1400, there is not a clear association between pogroms and the religion that the city would adopt in 1546. Instead, in the centuries 1500-1700, pogroms are more concentrated in areas that were Protestant in 1546. This shift in anti-Semitism towards Protestant areas can be clearly see in the data also in the 1700s (see Figure A.6) and in the 1800s (see Figure A.7), although pogroms are rarer in these last two centuries.

After having taken a first glance at the raw data, we start our regression analysis with a basic difference-in-differences setup:

$$Y_{it} = \alpha \text{Protestant}_i \text{Post}_t + X_{it} \beta + \gamma_i + \gamma_t + \varepsilon_{it} \quad (2)$$

where i is a city in the *Städtebuch*, and t is one of four centuries $t=1300-1400, \dots, 1600-1700$.⁴² Post_t is a dummy variable for the centuries 1500-1600 and later. Prot_i denotes whether a city was Protestant a few decades after the Reformation in 1546. X_{it} denotes a vector of control variables. Importantly, all regressions use city and century fixed effects. To the extent that there

⁴⁰ Figure A.18 in the Appendix reproduces a figure from Eisner (2003) that illustrates the trend in homicide rates in Germany and Switzerland between 1200 and 2000.

⁴¹ The originally higher pogrom intensity in Catholic cities is consistent with the idea that larger cities are more likely to experience pogroms and with the fact that, as Cantoni (2015) writes: “cities of the Protestant camp start off smaller in 1300”.

⁴² In the working paper version of this paper (Becker and Pascali, 2016), we used six centuries, 1300-1900, as our benchmark time frame and results in this extended sample are very similar. (We also prove the robustness of our main results in this extended sample in a set of robustness checks reported in the Appendix). To the extent that the overall pogrom intensity drops a lot after 1700, the difference between Protestant and Catholic cities is smaller in the 18th and 19th century.

are any unexplained time-constant differences between cities in their likelihood of persecuting Jews, they are addressed by city fixed effects. We cluster standard errors at the city level.

We also estimate a more flexible specification that would allow us to test for pre-trends in anti-Semitism and that takes the following form:

$$Y_{it} = \sum_{t=1400}^{1600} \alpha_t \text{Protestant}_i + X_{it}\beta + \gamma_i + \gamma_t + \varepsilon_{it} \quad (3)$$

where we let the coefficient on the interaction term vary over the centuries. It is important to note that in this specification, the estimated coefficient α_t must be measured relative to a baseline time period, which we take to be the 14th century.⁴³

Table 2 displays the results of regressions based on equations (2) and (3). In columns 1 through 4, the centuries 1300-1400 and 1400-1500 are combined as pre-Reformation, and the centuries 1500-1600 and 1600-1700 are combined into a post-Reformation period. These regressions only have one difference-in-differences coefficient that shows how anti-Semitic acts differ before and after the Reformation across cities that became Protestant and those that remained Catholic. Column 1 shows that after the Reformation, cities that became Protestant experienced an increase in anti-Semitic acts relative to cities that remained Catholic. The difference of 7 percentage points is quite substantial considering that the average frequency of city-by-century observations with anti-Semitic acts is 15.5 percent. In column 2, we control for presence of a Jewish community in a given century. It is important to stress that the presence of a Jewish community is by no means a prerequisite for a pogrom because there may be fewer than 10 Jewish families in a city, or Jews may be persecuted while traveling through a city. Interestingly, the main difference-in-differences coefficient is barely affected when controlling for presence of a Jewish community. In columns 3 and 4, we restrict the sample to cities with evidence of Jewish presence before 1500. The difference-in-differences coefficient becomes more pronounced in this subset of cities. In columns 5 and 6, we display results from estimation of equation (3), where coefficients vary by century. The results from column 5 are also displayed in **Figure 2**. This specification is interesting for two reasons. First, it allows us to check whether there is a pre-trend in anti-Semitism before the Reformation. Second, it allows us to see whether

⁴³ As a robustness check, we run regressions where we drop the 13th century, or the 14th century, or where we exclude Black Death pogroms. This is to make sure that our results are not driven by the choice of reference century, or by Black Death pogroms in particular. These results are reported in **Table A.4**.

there is a shift in anti-Semitism immediately after the Reformation or whether it takes time to develop. Relative to the base century 1300-1400, Protestant cities in 1546 are not more likely to have pogroms in 1400-1500, the century just before the Reformation. The coefficient of 0.00215 is very small and statistically insignificant. This finding supports the hypothesis that the simple pre-post Reformation difference-in-differences setup in column 1 does not identify a secular trend but rather a genuine shift after the Reformation. At the same time, the pogrom intensity is larger in Protestant cities from the Reformation century 1500-1600, and the coefficients in the subsequent century remains large and statistically significant.

The Appendix tables show various robustness checks. First, we show the robustness of our results to different sample of cities. **Table A.5** starts from the main sample of 1,274 cities and one by one excludes each of the eighteen regions in the *Deutsches Städtebuch* to probe robustness to outlier regions. **Table A.6** shows the equivalent of Table 3 for *all* cities in the *Städtebuch*, including those in East Prussia and those that did not host any Jewish communities (10+ families) for a total of 2,344 cities. In all cases, estimates are practically unchanged with respect to Table 2. In **Table A.7**, we reproduce Table 2, using both the set of cities and the definition of a city being Protestant from Cantoni (2012). The sample drops to 213 cities. The estimated coefficient on the interaction term remains positive and significant, although larger than in previous estimates reflecting the fact that cities in Cantoni are larger and are generally characterized by larger Jewish communities and more frequent pogroms.

We also show that results are not driven by a particular century or a particular wave of pogroms: In columns 1 and 2 of **Table A.8**, we exclude one by one each century before the Reformation, while in column 3, we re-run the difference-in-differences analysis excluding the Black Death pogroms (1347-1350). **Table A.9** confirms that our results are still valid when we extend the analysis until 1900. **Table A.11** does one further step and show the persistence of the change in the geography of anti-Semitism caused by the Reformation to the 19th century. To do this, it uses data about pogroms in 1348 and anti-Semitism in the early 1900s (measured as pogroms in 1920, votes for the Nazi Party, deportations after 1933, attacks on synagogues, and letters to *Der Stürmer*) from Voigtländer and Voth (2012).⁴⁴ We run a two-period difference-in-differences regression (pogroms in 1349 and anti-Semitic acts in the 1920s-1930s), on a smaller set of cities,

⁴⁴ We are grateful to Joachim Voth and Nico Voigtländer for sharing their data with us.

and find similar evidence as in our larger panel. **Table A.10** shows descriptive statistics for this sample.

The results in Table 2 might be driven by confounding factors. One factor that comes to mind is that some cities might be involved in war activities more often and that these violent activities might affect the Jewish community in the city or Jews coming to the city on business. In **Table 3**, column 1, we control for different indicators of war activity in which a city is involved. Although some indicators of war activities affect the pogrom intensity, the main difference-in-differences coefficient remains unaffected. War activities do not explain away the Reformation effect identified in Table 2.

Column 2 examines the importance of education, which *ex ante* could go both ways. To the extent that increased human capital investment allows Protestants to enter high-skilled occupations such as moneylending, these human capital investments alone might explain the shift in anti-Semitism towards Protestant areas. Although the presence of a school is associated with more pogroms, again, the main difference-in-differences coefficient remains unaffected. This finding does not contradict Botticini and Eckstein, whose focus is on the role of human capital investments in driving Jewish occupational specialization. Our results merely show that schooling *alone* does not explain the change in geographic patterns of anti-Semitism that followed the Reformation.

Finally, we control for population size. As described in the data section, when using population size as a regressor, we draw on Cantoni (2015) who relies on Bairoch et al. (1988) data. We first show, in column 3, that our results hold up in this smaller subsample. The coefficient estimate in the first row is considerably larger. To the extent that the Cantoni/Bairoch sample is a sample of larger cities that reach at least 5,000 inhabitants by 1800, the results indicate that the shift in anti-Semitism is even more pronounced when looking at this set of larger cities. Now, using this subsample, we include population data as a control variable and show that the main results remain the same. The point estimate in the first row remains the same, and population size as such does not seem to matter for pogrom incidence.

We take the combined results in Tables 2 and 3 (and in Appendix Tables A5-A9) as evidence that the Reformation brought about a change in the geography of anti-Semitism, namely, a shift toward Protestant cities. This shift is not explained by pre-trends or different location patterns of Jews before or after the Reformation or by war activities, education or

population size. We argue that this shift relates to economic factors, and we document this in section IV.C. However, before doing so, we want to further examine the Reformation period to determine whether the shift in anti-Semitic sentiments developed slowly over time or could be seen quite soon after 1517. To this end, we use book titles from which we infer anti-Jewish content.

IV.B. Anti-Semitism in book titles: 1451-1600

The decades before and after the Reformation are particularly interesting. Although our main analysis covers several centuries, we also pay particular attention to the decades around the Reformation. In particular, for the decades from 1451 to 1600, we capture city-level anti-Jewish attitudes using new data on the anti-Jewish books and pamphlets that were published in the city. The underlying assumption is that the books produced measure the supply of and demand for content in that city.⁴⁶ The use of anti-Jewish publications as a measure of anti-Semitism has two closely related advantages with respect to using the incidence of pogroms. First, pogroms, though terrible, do not occur at very high frequency.⁴⁷ Second, anti-Semitic sentiment is likely to be around, even when no pogrom occurs. A higher data frequency allows us to zoom in closer to the Reformation and to capture underlying sentiment. The main disadvantage of using anti-Jewish publications is the smaller number of cities in which books were published: instead of more than thousand cities, we have just above 100 cities with at least one print edition.

Before turning to regression analysis of the data described in Section III.B, we give a graphical presentation of the data. **Figure 3** shows the number of cities publishing (any) anti-Jewish books in each decade, separately for Catholic and Protestant cities. **Figure 4** shows the number of anti-Jewish books published in each decade, again separately for Catholic and Protestant cities. Both figures show very clearly that, after the Reformation, the printing of anti-Jewish material increased significantly in Protestant cities. A large part of this is, however, explained by the fact that printing went up a lot in Protestant cities overall, whether of an anti-

⁴⁶ Dittmar (2011) cites Edwards (1995), who observes, “If, for example, there was an interest in Strasbourg for a work first published in Wittenberg, it was more common for a printer in Strasbourg to reprint the work than it was for the printer in Wittenberg to ship a large number of copies [500 kilometers] to Strasbourg.” Dittmar provides additional evidence that in a first approximation, equating the place of print with local demand for these books is an acceptable assumption.

⁴⁷ Only one-quarter of the cities in the full sample documented at least one episode of killings or expulsions of Jews over the years 1300-1900.

Jewish nature or not. In the regression analysis below, we take the more conservative approach of controlling for the overall printing activity of a city, i.e. essentially measuring the share of books with anti-Jewish content. We would like to stress, however, that one could well argue that *not* controlling for overall printing activity, i.e. what is displayed in Figures 3 and 4 is the relevant exercise. The idea is that the mere existence of a larger number of books with anti-Jewish content means that the ideas expressed therein are diffusing in a city, independently of how much other material on various topics is around. Still, to rather err on the side of conservatism, in the following regressions analysis, we do control for total printing activity.

Using the equivalent of equations (2) and (3) at the decade level and restricting the sample to printing cities with books documented in the USTC, we can estimate whether there was a geographic pattern in anti-Semitic printing before and after the Reformation, whereby Protestant cities developed differently from Catholic cities. Note that in this exercise, we define “post-Reformation” as 1510 onwards. Although the Reformation took place in 1517, the decade from 1510 to 1519 is the decade of the Reformation, and the printing of Luther’s works started immediately after 1517, or within this decade. The results are robust to defining the post-Reformation period as 1520 onward.

Table 4 displays the results of this analysis. As expected, the estimated α is positive, statistically significant and has a value of 0.0673. This finding reflects the fact that following the Protestant Reformation, the number of anti-Jewish books published in reformed cities is higher by 7 percent relative to what happened in Catholic cities. Note that in all regression we control for the total number of books printed in a city. Remember that in most regressions of Table 4, we drop cities, which have a different religion with respect to the surrounding territory. One exception is column 2, where we also include printing cities whose religious denomination differs from the surrounding territory. Results there are weaker: the diff-in-diff coefficient drops by approximately a third and statistical significance falls marginally below conventional confidence levels (p-value=11%). This is in line with the idea that in the additional cities entering the sample, printers provide for a split market, reducing differences between Protestant and Catholic cities. In column 3, we allow difference-in-differences coefficients to vary decade by decade, in a specification similar to (3). The estimated α coefficients oscillate around 0, are small and never statistically significant in the decades 1460-1469 to 1500-1509. Starting with the decade 1510-1519, in the aftermath of the Reformation, the estimated α coefficients are positive

in all 9 post-Reformation decades and statistically significant (3 times out of 9 decades). This finding supports the hypothesis that the simple pre-post Reformation difference-in-differences setup in columns 1 and 2 does not identify a secular trend but rather a genuine shift in anti-Semitism after the Reformation.

Although the results in columns 1 to 3 consider the set of cities that had at least 20 book editions until the year 1600, columns 4 to 6 consider different subsamples. Column 4 repeats the analysis of column 1 for cities with at least 50 book editions until 1600. Column 5 considers all cities with a printing press and at least 100 printed editions until 1600. Column 6 restricts the analysis to cities with at least 1 printed book. In all regressions in columns 4 to 6, the results from column 1 are confirmed. **Table A.12** shows a further robustness check: using the set of 74 cities used in Table 4, column 1, we drop one decade at a time, to see whether results are driven by the inclusion/exclusion of one specific decade. Results are stable.

To conclude, after the striking evidence presented in Figures 3 and 4, which we consider to be relevant in its own right, even the results controlling for total volume of printing in Table 4 and in Appendix Table A.12 indicate a shift in anti-Jewish sentiment, following the Reformation, towards Protestant cities.

IV.C. The Economics of Anti-Semitism in the Century before and the Century after the Reformation

The estimates reported in Tables 2-4 show that Jewish pogroms, expulsions of Jews and anti-Jewish publications increased in Protestant areas relative to Catholic areas following the Protestant Reformation. How is this result related to the change in the ethics of usury induced by the Reformation?

To answer this question, we return to the sample of cities from the *Deutsches Städtebuch* used in Tables 2 and 3. We cannot use data on anti-Jewish publications because the cities with a printing press are too few to split the sample and still have enough power to identify the relevant coefficients. In **Table 5**, we first divide the sample depending on whether there is evidence of Jewish lending before the Protestant Reformation and re-estimate equation (2). There is an increase in anti-Semitism in Protestant cities relative to the Catholic ones, but the shift is stronger in those cities in which the Jews had been moneylenders (column 3), whereas the shift is smaller in the rest of the sample (column 1). Specifically, the estimated difference-in-differences

coefficient is three times as big in cities with evidence of Jewish lending before the Reformation. This result is robust to controlling for Jewish presence in the city (columns 2 and 4). Overall, these findings corroborate the view that the Protestant Reformation had an impact on anti-Semitism that works to a large extent via its effects on the ethics of usury.

A more rigorous way to illustrate the differential impact of the Protestant Reformation on anti-Semitism in places in which Jews were moneylenders versus places in which they were not is to estimate the difference-in-difference-in-differences specification reported in the following equation:

$$Y_{it} = \alpha(Prot_i \cdot Post_t \cdot JewLending_i + \sum_{t=1400}^{1600} \eta_t^P Protestant_i + \sum_{t=1400}^{1600} \eta_t^{JL} JewLending_i + X_{it}\beta + \gamma_i + \gamma_t + \varepsilon_{it}) \quad (4)$$

where $JewLending_i$ is a dummy variable that identifies those cities for which there is evidence of Jewish lending before 1500. The second and the third terms on the right-hand side of the equation are summations over all centuries in the sample, except for the first one, which is the reference century. The second term controls for differences in the evolution of anti-Semitism between Protestant and Catholic places, whereas the third one controls for differences in the evolution of anti-Semitism between cities with and without Jewish lending before 1500. Finally, we control for city- and century-fixed effects, and X is a vector of additional control variables.

We would like to emphasize that we do not assume that the cities in which Jews were moneylenders in 1500 are randomly distributed. These cities are clearly very different across several dimensions (for instance, they are larger and more involved in trade and manufacturing), which might have an impact on anti-Jewish sentiments and acts. We account for this by controlling for city-fixed effects and for the interaction between Jewish lending before 1500 and century-fixed effects. Columns 5 and 6 reports the coefficient on the triple interaction term. As shown, the triple interaction is statistically significant (the coefficient is 0.0982). This confirms that the great majority of the shift in anti-Semitism towards Protestant cities, that followed the Reformation, is explained by changes that happened in cities in which the Jews used to be moneylenders, while there is not much action in the rest of the sample.

However, despite controlling for various fixed effects as described above, we might still capture a lower bound of the impact of the Protestant Reformation in cities with Jewish lending. In fact, in these cities, although the rise of business rivalries might have increased anti-Semitism, the presence of a powerful Jewish bourgeoisie might have partially shielded the Jewish minority. In principle, this problem could be solved if we were able to measure the “need” for moneylending rather than the presence of Jewish lenders before the Reformation. To construct such a measure, we use data on the economic specialization of the city. In particular, we construct four dummy variables describing whether there is evidence of specialization in the city before 1500 in agriculture, manufacturing, trade, or other industries, respectively, relative to no industry information at all. We use these data as instrumental variables and estimate equation (4) by 2SLS, as follows:

$$\text{Second stage: } Y_{it} = \alpha(\text{Prot}_i \cdot \text{Post}_t \cdot \text{JewLending}_i^{\text{pre1500}}) + \sum_{t=1400}^{1600} \eta_t^P \text{Protestant}_i + \sum_{t=1400}^{1600} \eta_t^{JL} \text{JewLending}_i^{\text{pre1500}} + \sum_{s=ag,ma,tr,ot} \sum_{t=1300}^{1600} \eta_t^S I(s_i^{\text{pre1500}}) + X_{it}\beta + \gamma_i + \gamma_t + \varepsilon_{it}$$

$$\text{First stage: } \text{Prot}_i \cdot \text{Post}_t \cdot \text{JewLending}_i^{\text{pre1500}} = \sum_{s=ag,ma,tr,ot} \text{Prot}_i \cdot \text{Post}_t \cdot I(s_i^{\text{pre1500}}) + \sum_{t=1400}^{1600} \eta_t^P \text{Protestant}_i + \sum_{t=1400}^{1600} \eta_t^{JL} \text{JewLending}_i + \sum_{s=ag,ma,tr,ot} \sum_{t=1300}^{1600} \eta_t^S I(s_i^{\text{pre1500}}) + X_{it}\beta + \gamma_i + \gamma_t + \varepsilon_{it} \quad (5)$$

where $s=\text{agriculture, manufacturing, trade, or other sectors}$.

We want to emphasize that we are *not* assuming that the sector specialization of German cities in 1500 was random. Cities that specialized in different sectors differed across several dimensions that are captured in the 2SLS regressions by the city fixed effects. Moreover, we add sector-by-century fixed effects $\sum_{s=ag,ma,tr,ot} \sum_{t=1300}^{1600} \eta_t^S I(s_i^{\text{pre1500}})$ in the regression to control for the fact that the geography of pogroms might have evolved differently for cities that specialized in different sectors.

The exclusion restriction amounts to assuming that the way the pre-Reformation sectoral specialization of a city differentially affects the pogrom intensity of Protestant and Catholic cities before vs after the Reformation works through influencing the probability of pre-Reformation money-lending, but has no other direct effect on pogroms that differentially affects Protestant vs

Catholic cities before vs after the Reformation. Again, this is conditional on century-by-(pre-1500)-sector fixed effects.

The results are reported in **Table 6**. In column 1, as expected, the difference-in-difference-in-differences coefficient is larger in the 2SLS estimates than in the OLS estimates. Moreover, as with the OLS estimates, 2SLS results are robust when controlling for the presence of a Jewish community (column 2). A potential problem with the 2SLS estimates is that larger cities have more information regarding the industries that operated there before 1500. For this reason, in column 3, we control for the number of industries that are mentioned in the *Städtebuch* as operating in the city before 1500. Again, the results are practically unchanged. In column 4, we restrict the analysis to cities with confirmed Jewish presence before 1500 and find results confirmed. Finally, we go back to the smaller sample of cities with population data in Bairoch (column 5) and control for total population (in column 6).

A potential confounding factor is that the sectoral specialization before 1500 might be a measure of the level of economic success of the city before 1500. More specifically, our results might capture the fact that the Protestant Reformation could have induced a differential impact on anti-Semitism depending on the level of development of the city. The estimates reported in columns 5 and 6 exclude this possibility. In column 5, we limit the analysis to cities/centuries for which population data are available in Bairoch. Population figures for these cities are our best estimates of their economic success. As shown in column 6, when controlling for population, the main difference-in-difference-in-differences coefficient remains unaffected with respect to column 5. In both columns 5 and 6, this coefficient is larger with respect to our benchmark estimates in column 1 (0.927/0.920 vs 0.562) but is not statistically significant, a consequence of the fact that, when controlling for population, our sample drops from 1274 cities to 96 cities.

Tables A.13 through A.17 present various robustness checks: **Table A.13** drops one of eighteen regions in the *Deutsches Städtebuch* at a time. **Table A.14** uses all 2,344 cities in the *Deutsches Städtebuch*. **Table A.15** uses all 2,344 cities in the *Deutsches Städtebuch*. **Table A.16** excludes either the 13th or the 14th centuries, or the Black Death pogroms. **Table A.17** uses six centuries of data, from 1300-1900. All of the robustness checks broadly confirm our findings in the main sample.

In conclusion, Tables 5 and 6 provide evidence that the increase in anti-Semitism following the Protestant Reformation was far more pronounced in Protestant areas with a greater need for local

moneylenders. This result is not explained by a particular region or a particular century, and it does not depend on the source we use for the religion adopted by German cities following the Reformation. It is still valid when we extend the analysis either including the 1700s and 1800s or to cities that never hosted Jewish communities. This finding is consistent with our assumption that the Catholic ethics of usury partially shielded the Jewish minority in cities in which Jewish moneylenders were particularly needed. When the Reformation erupted, Jews lost their prerogatives in these cities and were exposed to competition with the Christian majority; this eventually resulted in a shift of anti-Semitic acts towards these areas. In the next section, we will document how the Protestant Reformation led the Jews to specialize in different sectors while maintaining their specialization in banking and finance in Catholic areas. We will also show that the impact of the Protestant Reformation on the geography of anti-Semitism persisted for at least four centuries and can be used to explain the emergence of the first anti-Semitic parties in the German Empire.

V. 19th-century Prussian county-level data

Census data from Prussia allow us to study in detail the economic geography of Jewish life and anti-Semitism at the end of the 19th century. The Prussian Statistical Office collected an impressive amount of data, the quality of which is generally accepted as having been outstanding already in the 19th century and that have survived at the county level in the archives. Data from various censuses have been digitized and are publicly available in iPEHD (see Becker et al., 2014). Data from the 1882 Occupation Census contain the population number of Jews, Protestants and Catholics as well as their occupational specializations. The data count the number of workers in each of approximately 30 sectors separately by religious denomination. The data also allow us to look separately at those who are self-employed or company directors, so we can also separately examine employment by hierarchical level.

To measure anti-Semitism in the same period, we use election data from elections to the Lower House of the German Empire parliament (the *Reichstag*) where, starting in 1890, anti-Semitic parties ran for parliament. Anti-Semitic candidates did not run in all electoral precincts, giving us the opportunity to look at the extensive margin of anti-Semitic candidates as well as the intensive margin (i.e., the vote share for anti-Semitic candidates).

We run cross-sectional regressions as follows:

$$Y_i = \alpha + \beta \text{ShareProtestant}_i + X_i\gamma + \varepsilon_i \quad (6)$$

The dependent variable in **Table 7** is the share of Jews in the county in 1882. Column 1 displays the results from a bivariate regression of the share of Jews on the share of Protestants in a county. The coefficient of -0.00874 indicates that, on average, all-Protestant counties have a Jewish population that is 0.874 percentage points smaller than all-Catholic counties. Comparing this to a Jewish population share of 1 percent in the average Prussian county, this is a considerable difference and indicates that 350 years after the Reformation, Jews in Prussia are much more likely to co-reside with Catholics. Column 2 adds a list of control variables: the share of the population aged below 10, the share of females, the share born in the municipality, the share of Prussian origin, average household size, log population size, a dummy variable for counties that are currently in Poland, and the share of the county population living in urban areas.

To the extent that the Protestant population share itself is endogenous, we need to use an instrument for Protestantism. Becker and Woessmann (2009) propose distance to Wittenberg as an instrument, exploiting the concentric spread of the Reformation from Wittenberg, the birthplace of the Reformation. The first stage equation, complementing equation (6) is the following:

$$\text{ShareProtestant}_i = \delta + \theta \cdot \text{distWittenberg}_i + X_i\eta + \vartheta_i \quad (7)$$

Column 3 shows that the share of Protestants falls rapidly with distance to Wittenberg: every 100 km of distance to Wittenberg is associated with a drop of 9.27 percentage points in the share of Protestants. Using the exogenous variation in the share of Protestants generated by distance to Wittenberg, we confirm the negative effect of the share of Protestants on the share of Jews (see column 4). These results are confirmed in columns 5 and 6, where we add the same control variables used in column 2.

Table A.18 presents a placebo exercise in which we test whether the share of Protestants in 1882 “predicts” the presence of a Jewish community before 1500. We regress a binary variable

capturing evidence of a Jewish community (10+ families) before 1500 (based on the city-level information from *Germania Judaica*) on the share of Protestants in 1882. We find no statistically significant relationship in the OLS regressions in columns 1 and 2.

The estimates provided in Table 7 and A.18 document that the Protestant Reformation led to a movement in the Jewish population from Protestant to Catholic areas. While until 1500, Jews were equally distributed between areas that would become Protestant and areas that would stay Catholic, in 1882, they were clearly concentrated in Catholic areas. This result supports the view that the Reformation worsened the living conditions of Jews in Protestant relative to Catholic areas.

In **Table 8**, we look at election results for anti-Semitic parties. Every coefficient displayed in Table 8 stems from separate OLS or IV regressions for elections to the Reichstag in 1890, 1893 and 1898. Because anti-Semitic candidates do not stand in all electoral precincts, we run regressions on the vote share of anti-Semitic candidates as well as on binary indicators of whether anti-Semitic candidates stand in a precinct. Note that in all regressions, we cluster by electoral precinct because electoral precincts are typically composed of two or three counties. All regressions show positive coefficient estimates that are statistically significant in nearly all specifications. The magnitude of the effect in the IV specifications varies from .0307 in 1890 to .131 in 1898; that is, all-Protestant counties, compared to all-Catholic counties, have a 3-percentage-point higher vote share in 1890 and a 13-percentage-point higher vote share in 1898, on average. Overall, these findings support the view that the Reformation was responsible of a shift in anti-Semitism from Catholic to Protestant areas.

Finally, we look at the occupational specialization of Jews. In line with the rest of the paper, we concentrate on Jewish presence in banking and insurance. **Table 9** regresses the share of those working in banking who are Jews on the share of Protestants. The results show that in Protestant counties, Jews are less prominent in the banking and insurance sector than in Catholic counties. This is true both when looking separately at specialization in banking or in insurance as well as for both sectors combined. The results also hold, with smaller coefficient estimates, when we control for the size of the Jewish population. It is not surprising that some of the effect in columns 1 to 3 is driven by the size of Jewish population, which, as documented in Table 7, is larger in Catholic counties. Importantly, even conditional on Jewish population size, the specialization effect holds. In columns 5 to 8, we look specifically at occupational specialization among the self-employed and company directors. The coefficient estimates are even larger,

attesting to an even stronger complementarity between Catholics and Jews at upper hierarchical levels.

Table 10 goes beyond the results in Table 9 in two ways. First, it probes the robustness of the results when considering counties with a certain minimum number of employees in banking and insurance. It is important to note that the banking and insurance sectors were quite small in 1882. On average, 0.07 percent of the labor force worked in banking and insurance.⁴⁸ Several counties did not have a single employee (or only one, two, or three) in banking and insurance. It is therefore a useful exercise to consider the subset of counties with at least one, two, three, or four employees. The results in panel A confirm the previous findings: there is a stronger Jewish specialization in banking and insurance in Catholic areas. In panel B, we repeat the analysis of panel A using distance to Wittenberg as an instrument for the share of Protestants in a county. The results are broadly confirmed, although at a somewhat lower level of statistical significance.

Table 11 shows the results of a placebo exercise in which we attempt to determine whether there was a higher degree of Jewish specialization in banking in Catholic areas before the Reformation. We regress a binary variable capturing evidence of Jewish lending before 1500 (based on the city-level information from *Germania Judaica*) on the share of Protestants in 1882. We find no statistically significant relationship in the OLS regressions in columns 1 and 2 and, if anything, a positive coefficient in IV regressions. We take this as evidence that before the Reformation, there was not a stronger complementarity in Catholic areas compared to Protestant areas, but we do find this after the Reformation.

We can summarize the results in this section as follows: 350 years after the Reformation, the Jewish share of the population is lower in Protestant areas than in Catholic areas. The degree of anti-Semitism expressed by votes for anti-Semitic parties is larger in Protestant areas, and the share of bankers who are Jews is higher in Catholic areas than in Protestant areas, documenting a larger degree of complementarity between Jews and Christians in banking in Catholic areas than in Protestant areas.

VI. Conclusion

In the debate on the determinants of anti-Semitism, economic factors have received little attention. Although there is no doubt that cultural and political factors are at play, we show that

⁴⁸ For comparison, the financial sector in Germany today employs approximately 2.5 percent of the workforce.

economic factors also play a role. Using data on German cities and regions over six centuries, we show that the geography of anti-Semitism is related to the geography of economic interactions between the Jewish minority and the Christian majority. The Catholic ethics of usury and higher levels of human capital with respect to the majority population gave to the Jewish minority a comparative advantage in moneylending in Catholic regions. This produced a complementarity between Jews and Christians that was broken up in Protestant areas after the Reformation. Jews were by no means sheltered from pogroms even in Catholic areas, as evidenced by the well-known pogroms after the Black Death in 1349, well before the Reformation. However, our results document that anti-Semitic acts and attitudes became relatively more frequent in Protestant areas relative to Catholic areas after the Reformation. We show that this differential effect of the Reformation is largely driven by the set of cities with documented Jewish lending activity before the Reformation and that, after the Reformation, Jews lost their prerogatives in banking and finance in Protestant Germany but not in Catholic Germany.

Our findings are important for both researchers and policymakers. For researchers, they provide empirical evidence that systematically identifies the effects of the division of labor on anti-Semitism. Moreover, the dataset that underlies the research provides researchers with a new and extensive source of information covering anti-Semitism in German cities and counties over six centuries. For policymakers who are willing to learn from history, our results suggest that anti-Semitism, and inter-ethnic conflict more generally, does respond to economic incentives. This is an important finding in light of ongoing contemporary ethnic conflicts worldwide.

N observations	5096	5096	3180	3180	5096	5096

Note: The table reports OLS estimates. The unit of observation is cityXcentury. After Reformation is a dummy variable for centuries 1500-1600 and later, so after the Reformation in 1517. Protestant (1546) is a dummy variable that identifies cities that were Protestant in 1546. Presence Jewish Community is a dummy variable which is equal to one if there is any evidence of a Jewish community in the city. Standard errors (reported in parentheses) are clustered at the city level. *** significant at 1 percent; ** significant at 5 percent; * significant at 10 percent.

Table 3: Anti-semitism before and after Protestant Reformation: Robustness checks

	(1)	(2)	(3)	(4)

Note: The table reports OLS estimates. The unit of observation is cityXcentury. After Reformation is a dummy variable for centuries 1500-1600 and later, so after the Reformation in 1517. Protestant (1546) is a dummy variable that identifies cities that were Protestant in 1546. The sample in columns 3 and 4 is limited to cities with available urban population data (from Bairoch, Batou and Chevre (1988)) starting from 1500. Standard errors (reported in parentheses) are clustered at the city level. *** significant at 1 percent; ** significant at 5 percent; * significant at 10 percent.

N cities	1274	1274	1274	795	96	96
N observations	5096	5096	5096	3180	294	294

Note: The table reports 2SLS estimates. The unit of observation is cityXcentury. After Reformation is a dummy variable for centuries 1500-1600 and later. Jewish Lending pre 1500 is a dummy variable that identifies all cities with any evidence of Jewish lending before 1500. Protestant (1546) is a dummy variable that identifies cities that were Protestant in 1546. Presence Jewish community is a dummy variable which is equal to one if there is any evidence of a Jewish community in the city. Num Recorded Industries is the number of industries, which are active before 1500 in the city and are recorded in the Deutsches Städtebuch. The instruments are Agriculture<1500, Manufacturing<1500, Trade<1500, and Other Industries<1500 (dummy variables that identify cities with evidence of businesses operating in agriculture, manufacturing, trade or other industries before 1500) interacted with Post-Reformation* Protestant (1546). Standard errors (reported in parentheses) are clustered at the city level. *** significant at 1 percent; ** significant at 5 percent; * significant at 10 percent.

Table 7: Share of Protestants and Jewish presence (Prussia)

	(1)	(2)	(3)	(4)	(5)	(6)	(7)
	Dependent variable is:

Note: The table reports OLS and 2SLS estimates. The unit of observation is the Prussian county in 1882. The sample includes all Prussian counties (398 out of a total of 452) that host one of the 2,344 cities in the Deutsches Städtebuch. Controls: share age below 10, share females, share born in municipality, share of Prussian origin, average household size, ln(population size), Poland dummy, share of county pop in urban area. Heteroskedasticity-consistent standard errors (reported in parentheses). *** significant at 1 percent; ** significant at 5 percent; * significant at 10 percent.

2 Figures

Figure 1: Average share of cities with either killings or expulsions of Jews by century (Catholic vs Protestant cities)

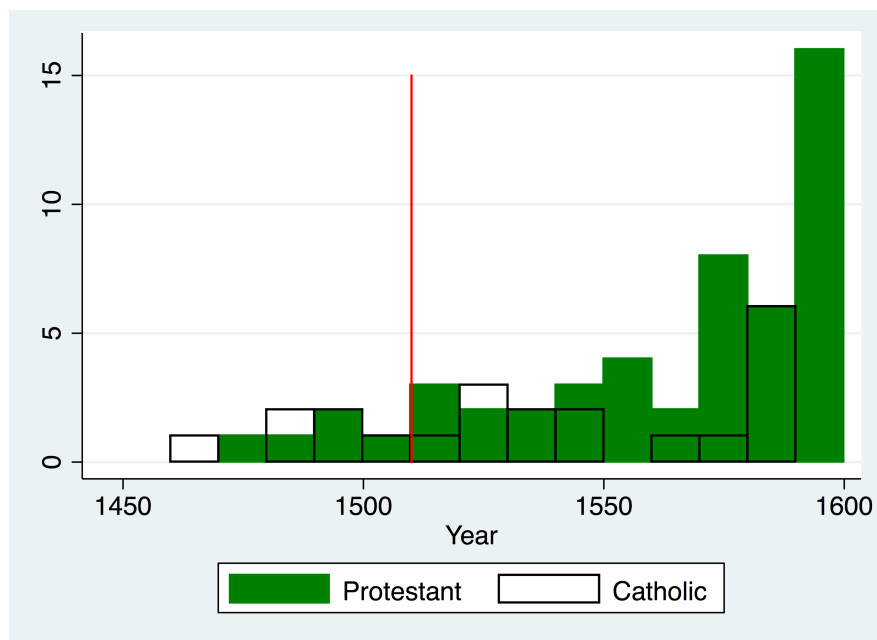

Note: The figure shows descriptive statistics for the set of 1,274 cities in the Deutsches Städtebuch over four centuries used in the main regressions.

Figure 2: Protestant (1546) X Century Indicator

Note: The figure displays coefficient estimates and confidence intervals from regression results displayed in Table 2, column 5.

Figure 3: Number of cities publishing anti-Jewish books in each decade: Catholic vs Protestant cities

Note: The data source is the Universal Short Title Catalogue (USTC). Book titles are classified as anti-Jewish using a naive Bayesian classifier (see main text for details).

Figure 4: Number of anti-Jewish books published in each decade: Catholic vs Protestant cities

Note: The data source is the Universal Short Title Catalogue (USTC). Book titles are classified as anti-Jewish using a naive Bayesian classifier (see main text for details).

A. Data Appendix (For online publication)

City-level data

City-level data are compiled from various sources, described in the main text. Here, we provide further detail and bibliographic references for the sources, and we describe how we coded our variables of interest. Our two sources of data on Jewish communities, anti-Semitic acts, and Jewish lending activity are the multi-volume *Germania Judaica* (1963–2009) for the pre-Reformation period and Alicke (2008), which covers the whole period but is our only source for the post-Reformation period. Importantly, Alicke and *Germania Judaica* coincide in capturing pogroms in the pre-Reformation period, but *Germania Judaica* has additional detail on Jewish lending; therefore, we rely on it for all of the pre-Reformation period.

Figure Data.1 describes how we code Jewish presence, Jewish lending, and pogroms/conflicts using the example of the city of Schwabach:

The image shows a page from *Germania Judaica* for the city of Schwabach. The page is titled "1332 Schwabach" and contains a section titled "*Schwabach". The text describes the city's location and history, mentioning Jewish presence and lending activity. Annotations with arrows point to specific parts of the text, explaining how they are coded into variables.

Annotations and corresponding codes:

- "Jews living in the city presumably since mid 14th century." → `community_1300_1400 = 2`
- "dispute due to outstanding debts" → `lending_pre1500 = 2`
- "1384 persecution of Jews in Schw. during which some Jews were killed" → `conflicts_1300_1400 = 6`
- "Despite several expulsions (1560, 1585), more or less continuously existing Jewish settlement until 1938" → `conflicts_1500_1600 = 4 , community_1500_1600 = 2`

Figure Data.1: Example of coding of Jewish presence, Jewish lending, and pogroms/conflicts based on the *Germania Judaica* for the city of Schwabach.

We use four different values for the **presence** of a Jewish community in a century:

999 The town is in the book but there is no relevant information about this variable

0 No (explicitly mentioned that Jews are not present in the city in that century)

2 Any mention of Jewish presence in the city

4 Evidence of a community of at least 10 families

Conflicts between Christians and Jews are coded as follows:

999 The town is in the book but there is no relevant information about this variable

0 No (evidence of a secure environment for the local Jewish community)

2 Small expulsion (single individuals or very few families)

4 Large expulsion (at least 3/4 of the community)

6 Some killings

8 Mass killings

In most of our analyses, we define pogroms as evidence of any expulsions or killings, so a value greater or equal than 2 in the categorization above.

Finally, evidence of **Jewish lending** is coded as follows:

999 The town is in the book but there is no relevant information about this variable

0 No (explicitly mentioned that Jews are not engaged in moneylending)

2 Jews explicitly mentioned to be engaged in legal lending

4 Jews explicitly mentioned to be engaged in illegal lending

In most of our analyses, we look at any evidence of Jewish lending, whether legal or illegal. Again, we want to stress a limitation of the data, namely that absence of proof is not proof of absence, but to our knowledge *Germania Judaica* is the best available data. Also note that we choose to code data century by century because the sources often do not give more precise information than that. In some cases, entries might just state that there is “evidence of a Jewish community during the x-th century”.

Similarly, we use Alicke (2008) to code up information on Jewish presence and on pogroms, as can be seen in Figure Data.2.

Schwabach (Mittelfranken/Bayern)

Die Wurzeln der jüdischen Gemeinde Schwabachs liegen im späten Mittelalter; 1337 wird erstmals die Existenz eines Juden in Schwabach erwähnt; 1384 soll es hier zu einem Pogrom gekommen sein.

In Schwabach konnte sich seit dem 16. Jahrhundert zunächst kaum jüdisches Leben etablieren; immer wieder setzte sich der Schwabacher Rat beim Markgrafen mit seiner Forderung durch, keine Juden in der Stadt dauerhaft ansiedeln zu lassen. Nach Ende des Dreißigjährigen Krieges erfolgte dann ein steter Zuzug jüdischer Familien nach Schwabach, der sich im 18. Jahrhundert noch verstärkte. Diese bildeten nun eine Kultusgemeinde. Die hiesigen Juden waren Händler mit weitreichenden Geschäftsbeziehungen.

Seit 1707 residierte in Schwabach der Landesrabbiner, was die Bedeutung Schwabachs als religiöses Zentrum der markgräflichen Landgemeinden zeigt.

An der Stelle eines älteren Synagogenbaus aus dem Jahre 1687 ließ die Schwabacher Judenschaft 1799 einen Neubau errichten.

“1337 first mention of a Jew’s existence in Schwabach.”

“A pogrom supposedly occurred here in 1384.”

“Jews began to continuously settle in Schwabach after the 30-years war with an increasing tendency in the 18th century.”

community_1600_1700 = 2
community_1700_1800 = 4
community_1800_1900 = 4

Figure Data.2: Example of coding of Jewish presence, Jewish lending, and pogroms/conflicts based on Alicke (2008) for the city of Schwabach.

Our source for further city-level data is the Deutsches Städtebuch. We use it to code up variables measuring the existence of a school (we note the first year a school is mentioned), a city’s involvement in military conflict, important/salient industries in a city’s economic activity, and population size. While it seems obvious how we code up the first year a school is mentioned (our measure of a city’s human capital investments) and population size, in Figure Data.3 we illustrate how we code information on military activity and Figure Data.4 how we code up industrial structure:

10 b Die Plünderung und Zerstörung durch Wallensteinische Truppen 1632 und spätere Truppendurchzüge im 30jähr. Krieg vernichteten große Teile der Bevölkerung und der Gebäude.

“Looted and destroyed by Wallenstein in 1632.”

“several march-throughs during the 30-years war”

Figure Data.3: Example of coding of battles based on the *Deutsches Städtebuch* for the city of Schwabach.

8 a Bierbrauerei (Stadtsiegel 1371: zwei gekreuzte Bierschapfen, 1330 Hopfengärten, jedes Stadtviertel hatte 1530 ein Erbbrauhaus). Messerschmiede 1400. Nadler und Goldschläger 1572 erw. Am Wege der Italienfahrer und an der Handelsstr. Nürnberg–Nördlingen–Augsburg gelegen. Kasten 1329 erw. Markt für die Bauern der „Hofmark“ und des späteren Amtes. 1410: 2 Jahrmärkte Johannes der Täufer und Martini. 1530: 8 Märkte Wunnibald, Richard, 3. Osters- tag, 3.  1572: Gold smith ->NACE: 27410

Figure Data.4: Example of coding of industries based on the *Deutsches Städtebuch* for the city of Schwabach using 5-digit NACE sector codes.

County-level data from Prussia

The county-level data available for Prussia in the 19th century are generally viewed as a unique source of highest-quality data for micro-regional analyses (Galloway, Hammel, and Lee (1994)). We have compiled the county-level data used in this paper from several censuses.

The 1882 Occupation Census

The 1882 Occupation Census (*Berufsstatistik vom 5. Juni 1882*) collected information on employment across two-digit sectors. Employment is listed separately for two groups: first, the self-employed and directors; second, administrative personnel and workers.

We calculate the share of the total labor force working in banking or in banking and insurance. We use the classification provided by the Prussian Statistical Office to classify the two sectors. We also calculate the share of the labor force in banking (or in banking and industry) who are Jews.

The source of the Occupation Census data are the Preussische Statistik (1884/85), Vol. 76c, pp. 284–386. Preussische Statistik (1884/85) Die Ergebnisse der Berufsstatistik vom 5. Juni 1882 im preussischen Staat. Preussische Statistik vol. 76. Berlin: Verlag des Königlichen Statistischen Bureaus.

1871 Population Census

The 1871 Population Census provides information on the share of different religious denominations – in particular, Protestants, Catholics, and Jews – in a county. In addition, the majority of our control variables is drawn from the 1871 Population Census, including a host of

demographic characteristics, literacy rates (measured as the ability to read and write among the population aged 10 years or older), and shares of the population with physical or mental disabilities (blind, deaf-mute, and insane). The source of the 1871 Population Census data is

Preussische Statistik (1875) *Die Gemeinden und Gutsbezirke des Preussischen Staates und Ihre Bevölkerung: Nach den Urmaterialen der allgemeinen Volkszählung vom 1. December 1871*. Berlin: Verlag des Königlichen Statistischen Bureaus.

Reichstag Election results 1890, 1893 1898

Election results for the lower House of the German Empire Parliament (“Reichstag”) are available at the level of electoral precincts. Those precincts remained unchanged throughout the years 1871-1914. Typically, an election precinct comprises two Prussian counties. In exceptional cases, there are one or three. In our analysis, we assign the same precinct-level election results to the Prussian counties nested in it. We cluster standard errors at the precinct level.

The sources of the election results are as follows:¹

- a) For 1890: Monatshefte zur Statistik des Deutschen Reichs 1890, April, pp. IV.23-IV.43. Edited by Kaiserliches Statistisches Amt, Berlin: Puttkammer & Mühlbrecht.
- b) For 1893: Vierteljahreshefte zur Statistik des Deutschen Reichs, 1893, vol. 2, pp. IV.2-IV.33. Edited by Kaiserliches Statistisches Amt, Berlin: Puttkammer & Mühlbrecht.
- c) For 1898: Vierteljahreshefte zur Statistik des Deutschen Reichs, 1903, vol. 12, pp. III.42-III.102. Edited by Kaiserliches Statistisches Amt, Berlin: Puttkammer & Mühlbrecht.

¹ Election data were downloaded from the Galloway Prussia Database (Galloway, 2007).

B. Appendix: quotes from Encyclopaedia Judaica about Jews and moneylending in German history (For online publication)

With reference to Middle Ages

"The city guilds forced the Jews out of the trades and the regular channels of commerce; this coincided with the stricter appliance of the church ban on usury in the 12th to 13th centuries. The combination of circumstances made moneylending and pawnbroking the main occupation of Jews in Germany." (vol. 7: pp. 519)

"However moneylending, conceived by the Church as usury, became the hallmark of Jewish life in Germany. About 100 to 150 years after usury became the main occupation of Jews in England and France, it became central to the livelihood of Jews in Germany also." (vol. 7: pp. 519)

"Even the source of livelihood that was forced upon the Jews -- lending money against interest -- came to be appreciated as an advantage since it left time to spare for Torah study. Moneylending also determined the artificial structure of Jewish life; the Jews derived their income mainly from non- Jews, and there was hardly any economic exploitation of one Jew by another. As a result, there was a large measure of social cohesion in the German communities." (vol. 7: pp. 520)

With reference to 14th century

"[...] the structure of Jewish life in Germany suffered a severe blow. Nevertheless, only a short while later, Jews were again permitted to take up residence in German cities, where there was no one else to fulfil their function in society of moneylenders." (vol. 7: pp. 522)

With reference to 16th century

"Jews were prohibited from practicing most occupations. Many now had to earn a livelihood from hawking haberdashery, peddling, moneylending, and pawnbroking in the small towns and villages." (vol. 7: pp. 524)

With reference to court Jews in 17th century and early 18th century

"A characteristic innovation of the era of absolutism and the mercantile system was the appearance of the Court Jews." (vol. 7: pp. 526)

"The rise of the absolute monarchies in Central Europe brought numbers of Jews, mostly of Ashkenazi origin, into the position of negotiating loans for the various courts, giving rise to the phenomenon of Court Jews. The most famous and most active of them in financial affairs were, in the second half of the 17th and the beginning of the 18th century, Leffmann Behrends in Hanover, Behrend Lehmann in Halberstadt, Bendix Goldschmidt in Hamburg, Aaron Beer in Frankfurt, and Samuel Oppenheimer and Samson Wertheimer in Vienna. Later Diego d'Aguilar, and the Arnstein and Eskeles families became prominent. In the early 18th century Joseph Suess Oppenheimer was the outstanding figure in southern Germany; his financial influence was widespread, especially in Wuerttemberg, until his fall and execution in 1738. Important court bankers around the end of the 18th century were Israel Jacobson in Brunswick, the Bleichroeder family in Berlin, Simon Baruch and Solomon Oppenheimer in Bonn, the Rothschilds in Frankfurt, the Reutlinger, Seligmann, and Haber families in Karlsruhe, the Kaulla family in Stuttgart, and Aron Elias Seligmann, later baron of Eichthal, in Munich." (vol. 14: pp. 440)

"From the 17th century onward [...] in spite of occasional regressions, a gradual improvement of the position of the Jews in Western Europe became noticeable. Money-lending still remained one of their main occupations, but they also traded, sometimes simultaneously, in all kinds of merchandise, or they earned their living as craftsmen and artisans." (vol. 14: pp. 441)

With reference to late 18th century

"Jews were active in the economy of the country and some became leading bankers, industrialists, and businessmen; there were also a large number of Jews in the liberal professions." (vol. 7: pp. 528)

With reference to 19th century and early 20th century "When Jews moved to western countries in the late 19th-early 20th centuries, moneylending was a frequent occupation, especially in the first and second generation, and the Jewish moneylender became a familiar stereotype." (vol. 14: pp. 443)

A C. Appendix: additional tables and figures (for online publication)

Table A.1: Descriptive Statistics by century

N observations	4752	4852	5060	4940	4596	4788

Note: The table reports OLS estimates. The unit of observation is cityXcentury. After Reformation is a dummy variable for centuries 1500-1600 and later, so after the Reformation in 1517. Protestant (1546) is a dummy variable that identifies cities that were Protestant in 1546. City and century fixed effects are included in the regression. Standard errors (reported in parentheses) are clustered at the city level. *** significant at 1 percent; ** significant at 5 percent; * significant at 10 percent.

Table A.11: Benchmark Estimates: Anti-semitism before and after Protestant Reformation (CITIES INCLUDED IN VV2012)

	(1)	(2)	(3)	(4)	(5)	(6)	(7)
	Dependent variable is antisemitism measured as 1349 pograms and:						
	1920s pograms	Synagogue attacks	NSDAP 1928	DVFP 1925	Deportations	Sturmer Letters	First Principal Component
Protestant (1546)	0.499*	0.0633	0.612**	0.544**	0.0598	0.0858	0.600**
X After Reformation	(0.293)	(0.200)	(0.243)	(0.253)	(0.213)	(0.230)	(0.249)
CENTURY FE	YES	YES	YES	YES	YES	YES	YES
CITY FE	YES	YES	YES	YES	YES	YES	YES
N cities	319	319	319	319	301	319	301
N observations	638	638	638	638	602	638	602
r2	0.643	0.719	0.677	0.643	0.720	0.667	0.684

The table reports OLS estimates. The unit of observation is cityXyear. After Reformation is a dummy variable that identifies the observations after 1517. Protestant (1546) is a dummy variable that identifies cities that were Protestant in 1546. Anti-semitism in the 14th century is proxied by 1349 pogroms, while anti-Semitism in the 20th century is proxied by either pogroms in the 1920s, or synagogue attacks in 1938, or vote share for NSDAP in 1928, or vote share for DVFP in 1925, or number of deportees from each locality, or number of anti-semitic letters to Der Sturmer, or from a first principal component of these six proxies. Standard errors (reported in parentheses) are two-way clustered (city and century). *** significant at 1 percent; ** significant at 5 percent; * significant at 10 percent.

N cities	1274	1274	1274
N observations	3822	3822	5096

Note: The table reports 2SLS estimates. The unit of observation is cityXcentury. After Reformation is a dummy variable for centuries 1500-1600 and later. Jewish Lending pre 1500 is a dummy variable that identifies all cities with any evidence of Jewish lending before 1500. Protestant (1546) is a dummy variable that identifies cities that were Protestant in 1546. Presence Jewish community is a dummy variable which is equal to one if there is any evidence of a Jewish community in the city. Num Recorded Industries is the number of industries, which are active before 1500 in the city and are recorded in the Deutsches Städtebuch. The instruments are Agriculture<1500, Manufacturing<1500, Trade<1500, and Other Industries<1500 (dummy variables that identify cities with evidence of businesses operating in agriculture, manufacturing, trade or other industries before 1500) interacted with Post-Reformation* Protestant (1546). Standard errors (reported in parentheses) are clustered at the city level. *** significant at 1 percent; ** significant at 5 percent; * significant at 10 percent.

Table A.17: The lending channel (part 2): 2SLS estimates. Robustness check: includes all centuries from 1300 to 1900

	(1)	(2)	(3)	(4)	(5)	(6)

Table A.18: Placebo. Share of Protestants in 1882 and Jewish communities before 1500 (Prussia)

	(1)	(2)
	Dependent variable is: Presence of a Jewish community before 1500	
	OLS estimates	
Share of Protestant 1882	-0.100 (0.0674)	0.0164 (0.0715)
Controls	NO	YES
r2	0.00557	0.216
N observations	398	398

Note: The table reports OLS estimates. The unit of observation is the Prussian county in 1882. The sample includes all Prussian counties (398 out of a total of 452) that host one of the 2,344 cities in the Deutsches Städtebuch. Controls: share age below 10, share females, share born in municipality, share of Prussian origin, average household size, ln(population size), Poland dummy, share of county pop in urban area. Heteroskedasticity-consistent standard errors (reported in parentheses). *** significant at 1 percent; ** significant at 5 percent; * significant at 10 percent.

Figure A.9: Word Cloud of anti-Semitic books

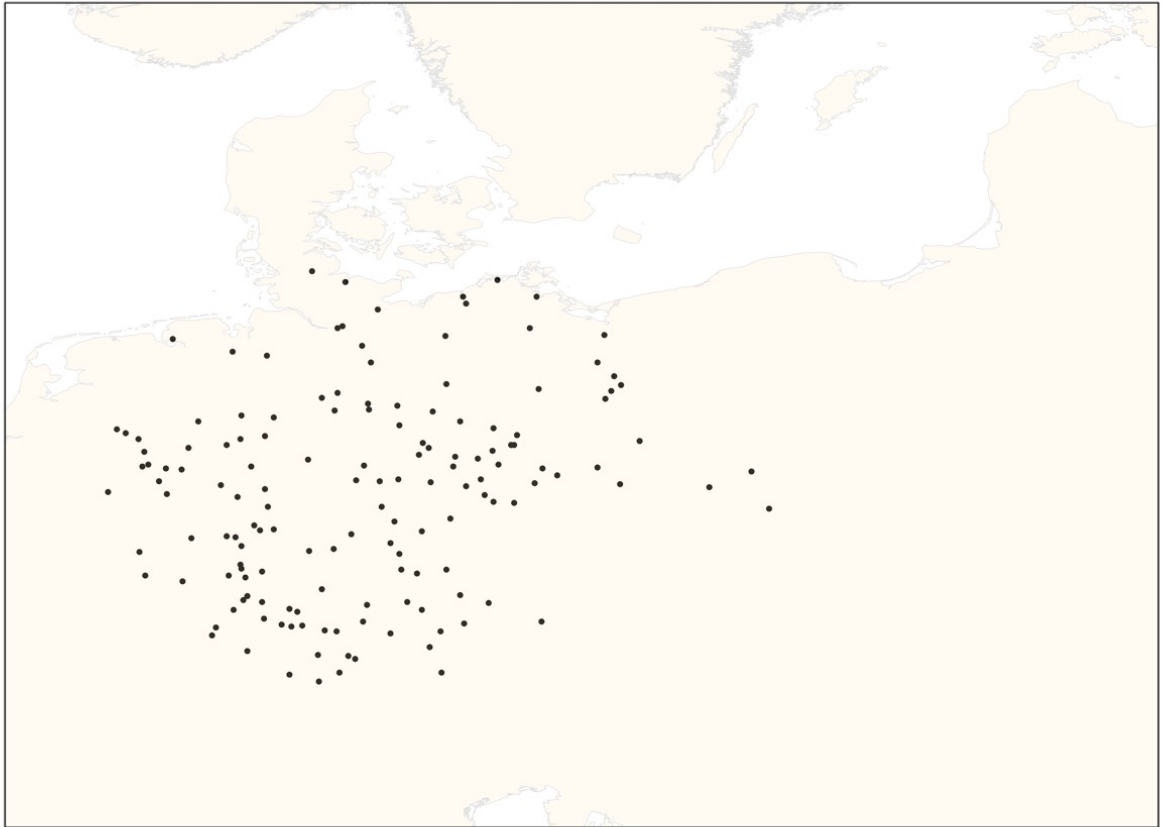

The word cloud displays the following text: **IUDEI** **CONTRA** **CHRISTIAN** **FIDEI** **CHRISTO**
ECCLESIA **CATHOLIC** **ERRORES** **HISTORIA** **ADVERSUS** **VERITATE** **PERFIDIA** **NICOL**
LYRA **OMNES** **ACCESSIT** **PROPHETA** **RELIGIONIS** **DOMINE** **SACRAMENTO** **FOENORE**
LATINA **MAHOMETI** **SCRIPTURA** **ROMA** **THEOLOGIA** **INFIDELES** **JOANN** **RABBI** **LIBELLO**

Note: The figure reports the word cloud for anti-Jewish Latin books. Not surprisingly, the most common words are *Contra* and *Iudei* (Against and Jews). Among the most frequent words, we also see *Errores* (Mistakes), *Adversus* (Enemy), *Perfidia* (Perfidy), *Foenore* (Usury), and *Infidels* (Infidels). See Section III.B for details.
