### P2P Lending: Information Externalities, Social Networks and Loans' Substitution

#### Ester Faia<sup>\*</sup> & Monica Paiella<sup>\*\*</sup>

\* Goethe University Frankfurt and CEPR. \*\*University of Naples Parthenope

### P2P lending developments

- P2P lending platforms: markets for consumer and business debt where lenders and borrowers match and trade directly, hence in absence of intermediation
- Emerged in 2005 (US Prosper). Highest growth in the aftermath of the crisis, in coincidence with the *fragility* of the banking system as well as the distrust of investors towards it
- Success story: relatively low loan rates and default rates down from 34% in 2009 to very low figures

### Main features of P2P markets

- Dis-intermediated, uncollateralized debt markets:
  - Asymmetric information
  - Availability of costless public signals that facilitate screening and mitigate lemon's market adverse selection
    - Hard information (FICO scores and other official credit-worthiness measures);
    - Soft information (e.g. recommendation from other investors);
    - Borrowers' self reports
  - Innovation in screening technology: machine learning collects and makes information public, mitigating adverse selection

### P2P lending markets: costs and benefits

#### • Borrowers:

- Lower costs, no need of collateral guarantees, no risk of early liquidation due to banks' liquidity shortages
- > Higher interest rates

#### • Lenders:

- Attractive returns (compared to standard investment by banks) and no risk of *haircut* due to banks' distress
- More risk (in the absence of a delegated monitor that screens and monitors projects)

### Our analysis

- General equilibrium model (focus on price formation)
  - 1. Households/investors/lenders solve dynamic portfolio problem
  - 2. Borrowers seek funds for projects of heterogeneous and unobservable quality
  - *3. a* P2P market (adverse selection):
    - > Distribution of loan rates with risk and information premia
    - Public signals reduce adverse selection and information premia
  - 3. *b* Traditional banks: competitive; subject to risk of distress
- Empirical analysis: US data from Prosper and Lending Club (merged with measures of bank fragility)

## Focus of the paper

- Assessment of the impact of information on P2P loan returns
  - Loan returns capture both default risks of projects and information premia due to asymmetric information

<u>Main result</u>: signals, of both *hard and soft* type, mitigate information premia

- Assessment of potential substitutability between digital platforms and traditional banking
  - Most of the increase in participation in the platforms seems to be due to erosion of trust in and perception of fragility of traditional banking sector

<u>Main result</u>: higher banking sector fragility (captured by currency-deposit ratio and bank failures) lowers P2P loan returns

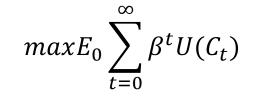

### Related literature 1/2

- Focus on the relationship between borrowers' attributes and listing outcomes in P2P markets
  - Pope and Syndor [2011, JHR] and Ravina [2012]: discrimination
  - Duarte, Siegel and Young [2012, RFS]: trust
  - Paravisini, Ravina and Rappoport [2017, MS]: risk aversion
- On asymmetric information and signals in P2P markets:
  - Freedman and Jin [2016]: learning by doing by returning lenders
  - Iyer, Khwaja, Luttmer and Shue [2016, MS] and Kawai, Onishi and Uetake [2016]: interest rates as a signal of creditworthiness

### Related literature 2/2

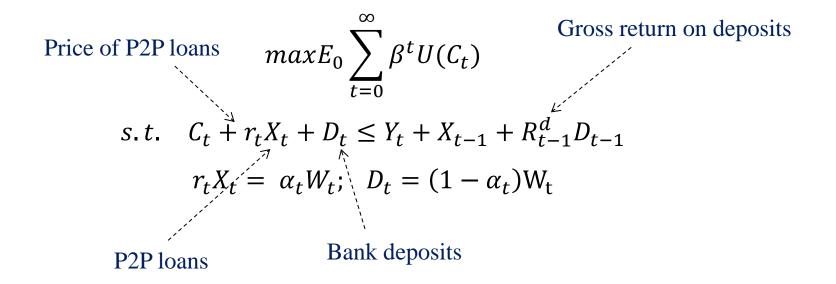

- No studies of the substitution between traditional banking and digital intermediation
- Literature on markets vs. banks (Allen and Gale, 1999 JFI; 2000)
  - In markets the relevant friction is information asymmetry.
    The crucial innovation of the P2P markets is the availability of public signals that lessen the information asymmetry.

#### Households/Lenders

s.t.  $C_t + r_t X_t + D_t \le Y_t + X_{t-1} + R_{t-1}^d D_{t-1}$  $r_t X_t = \alpha_t W_t; \quad D_t = (1 - \alpha_t) W_t$ 

#### Households/Lenders

#### Borrowers

- Risk neutral
- Projects quality is heterogeneous:

succeed and deliver  $R_t^I$ , with probability  $p^i$ , or fail and return zero:

$$p^i \in \mathbb{U}\left[\bar{p} - \frac{\varepsilon}{2}; \bar{p} + \frac{\varepsilon}{2}\right]$$

 $p^i$  is know to borrowers, but not to lenders

### Banks 1/2

- Costly screening technology: pay μ and learn project's quality (*p<sup>i</sup>*) perfectly
- Fragility risk, from liquidity shortage (e.g. run or liquidity freezes) or failure, with probability  $\zeta_t$
- With probability  $\zeta_t$ , bank liquidate projects early at a discount,  $\theta$
- Given the risk of distress, banks' expected return from project *i* is  $\bar{\theta}_t p^i R_t^I$ ,

where: 
$$\bar{\theta} = \theta \zeta_t + (1 - \zeta_t)$$

### Banks 2/2

- Banks are fully competitive; they fund loans with deposits; all project returns are rebated to depositors
- Banks realize returns only if projects are successful, but they have to pay depositors and the screening cost in any case
- In case of distress, absent insurance on banks' demand deposits, the loss from project early liquidation is eventually transferred onto depositors
- Depositors' expected return from deposits is  $\bar{\theta}_t R_t^d$

• Signals (as in Ruckes 2004, Petriconi 2016):

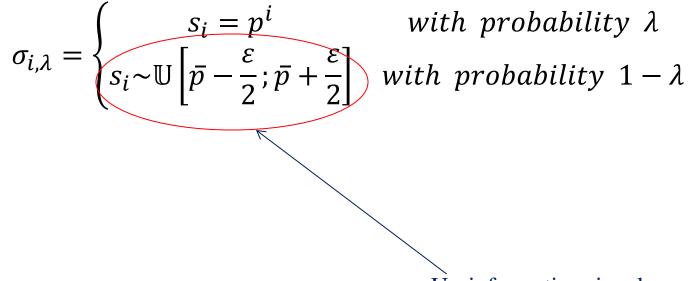

$$\sigma_{i,\lambda} = \begin{cases} s_i = p^i & \text{with probability } \lambda \\ s_i \sim \mathbb{U}\left[\bar{p} - \frac{\varepsilon}{2}; \bar{p} + \frac{\varepsilon}{2}\right] & \text{with probability } 1 - \lambda \end{cases}$$

Signals (as in Ruckes 2004, Petriconi 2016):

 $\sigma_{i,\lambda} = \begin{cases} s_i = p^i & \text{with probability } \lambda \\ s_i \sim \mathbb{U}\left[\bar{p} - \frac{\varepsilon}{2}; \bar{p} + \frac{\varepsilon}{2}\right] & \text{with probability } 1 - \lambda \end{cases}$ 

Fully informative signal

• Signals (as in Ruckes 2004, Petriconi 2016):

Un-informative signal

• Signals (as in Ruckes 2004, Petriconi 2016):

$$\sigma_{i,\lambda} = \begin{cases} s_i = p^i & \text{with probability } \lambda \\ s_i \sim \mathbb{U}\left[\bar{p} - \frac{\varepsilon}{2}; \bar{p} + \frac{\varepsilon}{2}\right] & \text{with probability } 1 - \lambda \end{cases}$$

• Once they receive the signal, lenders update their estimate of project's success probability which, given Bayesian updating of beliefs, results in the following posterior expectation:

$$E_t(p^i | \sigma_{i,\lambda} = s_i) = \lambda s_i + (1 - \lambda)\bar{p}$$

and the expected return from the project is:  $E_t(p^i | \sigma_{i,\lambda} = s_i)R_t^I$ 

## No arbitrage condition 1/2

- From households/lenders FOCs for P2P loans (X<sub>t</sub>) and bank deposits (D<sub>t</sub>),
- allowing for bank probability of distress (which affects lenders expected return from deposits,  $\bar{\theta}_t R_t^d$ ) ...
- allowing for signals (which affect the expected return from P2P loans,  $E_t(p^i | \sigma_{i,\lambda} = s_i) R_t^I)$ ,
- we obtain the following optimality condition (for given signal precision,  $\lambda$ ):

$$E_t(p^i | \sigma_{i,\lambda} = s_i) R_t^I = \frac{1}{\beta} E_t \left\{ \frac{U'(C_t)}{U'(C_{t+1})} \right\} = \overline{\theta_t} R_t^d$$

### No arbitrage condition 2/2

• The following optimality condition (for given signal precision,  $\lambda$ ):

$$E_t(p^i | \sigma_{i,\lambda} = s_i) R_t^I = \frac{1}{\beta} E_t \left\{ \frac{U'(C_t)}{U'(C_{t+1})} \right\} = \overline{\theta_t} R_t^d$$

It determines the P2P project that will be funded at the margin (threshold)
 Three testable predictions regarding P2P market liquidity and prices

### Substitution between banks and platforms

An increase in the risk of a shock in the banking sector (ζ) raises platform liquidity and lower P2P loans' returns (because it lowers expected defaults)

An increase in  $\zeta$  decreases the threshold of projects funded through P2P  $\rightarrow$  more projects go to the platform  $\rightarrow$  participation increases

Intuition: more borrowers with good projects are expected to choose P2P markets and more lenders do too.

Loan spreads decrease as lenders require lower returns on P2P loans.

$$E_t(p^i | \sigma_{i,\lambda} = s_i) R_t^I = \frac{1}{\beta} E_t \left\{ \frac{U'(C_t)}{U'(C_{t+1})} \right\} = \overline{\theta_t} R_t^d$$

### Information and selection

2) An increase in signal's precision, i.e. in the probability that the signal is informative,  $\lambda$ , increases platform liquidity, and reduces information premia.

Intuition: if signal precision increases, lenders are better at discerning the quality of projects. This reduces adverse selection and lenders are willing to receive lower returns.

3) An increase in the average quality of projects,  $\overline{p}$ , increases platform liquidity and lowers loans' returns.

### Prosper Data (2006-2014)

• Borrower personal profiles: amount requested, interest rate, term and purpose of loan

+ independently verified information on credit history (FICO score, open credit lines, delinquencies), income and other debts

- Prosper creates social networks:
  - links borrowers in groups (tied by geography, common interests, or common loan purpose)
  - collects endorsements of other Prosper members (friends)

### Prosper loans

- Loan size Min: \$1,000; max: \$35,000
- Term 12, 36, 60 months
- Fees of up to 2 percent of loan amount
- FICO>520
- Minimum bid: \$50
- In 2009, Prosper registered with the SEC and changed its business model from eBay-style auctions to rates determined by proprietary algorithm based on credit history, ect.

#### Summary statistics

| Year of the loan           | 2006              | 2007    | 2008    | 2009    | 2010    | 2011    | 2012    | 2013    | 2014    |

#### Loan riskiness

| Year of the loan      | 2006 | 2007 | 2008 | 2009 | 2010 | 2011 | 2012 | 2013 | 2014 | Total |
|-----------------------|------|------|------|------|------|------|------|------|------|-------|
| Completed             | 61%  | 61%  | 67%  | 85%  | 83%  | 49%  | 28%  | 7%   | 1%   | 34%   |
| Current               | -    | -    | -    | -    | -    | 29%  | 54%  | 89%  | 99%  | 49%   |
| Past Due (1-120 days) | -    | -    | -    | -    | -    | 3%   | 4%   | 3%   | -    | 2%    |
| Chargedoff            | 16%  | 26%  | 24%  | 11%  | 14%  | 16%  | 12%  | 1%   | -    | 11%   |
| Defaulted             | 23%  | 14%  | 9%   | 4%   | 3%   | 3%   | 2%   | 0%   | -    | 4%    |
|                       | 100% | 100% | 100% | 100% | 100% | 100% | 100% | 100% | 100% | 100%  |

- Decline in loan riskiness: the share of loans classified as 'Charged off' or in 'Default' was relatively high at the onset of the platform, but has fallen significantly after 2009
- In 2014, US banks charged off or reported as delinquent 16.6 percent of all consumer loans (18.5 percent in 2013)

#### Hard and soft information about borrowers

| Year of the loan                          | 2006    | 2007   | 2008   | 2009  | 2010  | 2011   | 2012   | 2013   | 2014   |
|---|---------|--------|--------|-------|-------|--------|--------|--------|--------|
| Mean FICO score                           | 609     | 654    | 674    | 715   | 714   | 709    | 711    | 708    | 703    |

# OLS regressions of lending rates on loan characteristics and signals

- Lending rates are decreasing in the FICO score, increasing in the number of credit lines and credit enquiries and for delinquent borrowers
- Once we control for credit risk, being part of group lowers the lending rate, by 0.5-2 p.p.
- Rates are lower for borrowers with funding from friends, by up to 4.5 p.p. before 2009, up to 1.5 p.p. after 2009
- Borrowers with prior loans pay 4 p.p less; the group dummy becomes insignificant and 'friends' variables coefficients become smaller

#### Lending rates and signal precision

#### Lending rates and signal precision

- No official documentation for income: 8% of sample
  - Borrowers whose income is verifiable pay 1 p.p. less
- No open credit lines → cannot tell whether more or less risky:
  1% of sample
  - Borrowers with no credit lines pay 2.4 p.p. more
- No state of residency: 30% of sample (pre-2009)
  - Borrowing rates 2 p.p. higher
- No reason for borrowing: 10% of sample (post 2009)
  - Borrowing rates 0.5 p.p. higher

#### Lending rates and banking panics

- Consistent with the predictions of our model, fragility of the banking sector increases investors participation in the platform; increased liquidity induces a decline in the rates
- The currency-deposit ratio varies over time. We include state and quarter dummies to control for aggregate shocks
- If the currency deposit ratio raises by 20%, rates drops by 1 p.p.
- Dummy for bank runs: small, but significant coefficient
- Small effect due to substitution through other instruments (besides P2P platform)

#### Bank runs

- 1. August 2007, Countrywide Financial suffered a bank run as a consequence of the subprime mortgage crisis;
- 2. March 2008, Bear Stearns suffered a run. Although it was not an ordinary deposit-taking bank, it had financed huge long-term investments by selling short-maturity bonds, making it vulnerable to panic on the part of its bondholders;
- 3. June 2008, mortgage lender IndyMac Bank suffered a run when a warning was issued that it might not be viable;
- 4. September 2008, Washington Mutual, the largest US savings and loan and the sixth-largest financial institution, was shut down due to a massive run.

#### Lending rates, **banking failures** and signals

## Concluding remarks

- P2P lending has experienced an impressive growth and has penetrated most markets including high growth ones like China
- Despite the lack of delegated monitor and the potential costs of asymmetric information, data suggest that it is performing well relatively to traditional banking, thanks to...
- 1. The digital technology allows *costless* access to information which increases market transparency and mitigates information asymmetry
- 2. In times of bank distress the platforms provide a valuable form of borrowing and investment substitution that improves risk-sharing
